It is possible to identify the origin of the utility scale by extending the choice task – for example, by including comparisons not only between single options but also between pairs of options. Böckenholt (2004) discusses different variations of the choice paradigm that can be used for this purpose. In general, methods for identifying a utility scale origin not only are instrumental for avoiding difficulties in the interpretation of the estimated parameters of a choice model, but also may provide useful insights about the underlying judgmental process.

Modeling Effects of Individual Differences, Time, and Social Dependencies

Over the years, the Thurstonian choice paradigm has been extended in different directions. Much work is underway to enhance the tool set for modeling individual differences both at a particular point in time and over time. There is also strong interest in going beyond modeling the relationship between choice options and decision makers and considering a wider range of factors, including social context and social influences.

Individual Differences

The analysis of individual difference effects is one of the most fruitful aspects of preference models. Past work considered nested and crossed random effects, person-specific regression weights, and factor structures to capture dependencies among options under flexible distributional assumptions that include mixtures of the extreme value distribution, multivariate normality, scale mixtures of multivariate normal distributions, and Dirchlet processes. For example, the following decomposition of an individual utility vector allows for the effects of person-specific covariates $\mathbf{x}_i$ as well as observed and unobserved attributes of the options, given by $\mathbf{M}$ and $\boldsymbol{\Lambda}$, respectively:

$$\boldsymbol{\mu}_i = \boldsymbol{\mu} + \mathrm{K}\mathbf{x}_i + \mathrm{M}\boldsymbol{\beta}_i + \boldsymbol{\Lambda}\mathbf{f}_i + \boldsymbol{\nu}_i \qquad [3]$$

where $\mathbf{K}$, $\boldsymbol{\beta}_i$, and $\mathbf{f}_i$ contain regression coefficients. Effects that are not accounted for by the covariates are represented by $\boldsymbol{\nu}_i$. Under normality assumptions, $\boldsymbol{\nu}_i \sim N(\mathbf{0}, \boldsymbol{\Sigma}_{\nu})$, $\boldsymbol{\beta}_i \sim N(\boldsymbol{\beta}, \boldsymbol{\Sigma}_{\beta})$, and $\mathbf{f}_i \sim N(\mathbf{0}, \boldsymbol{\Sigma}_f)$. A detailed discussion and application of this modeling framework is presented in Maydeu-Olivares and Böckenholt (2009), who first introduced the observed covariates describing the choice options and decision makers and then allow for unobserved option attributes to account for any remaining systematic variations in political preferences.

Although the interpretation of individual taste differences is much simplified under the assumption that decision makers use the same set of attributes in assessing the choice options, some care must be taken in relating these attributes to the option utilities. For example, the relationship between attributes and utilities may not be linear, as postulated by the factor-analytic model in [3], but nonmonotonic, as in the ideal-point model if individuals choose the option that is closest to their 'ideal' or most preferred option (Coombs, 1964).

Temporal Preferences

When preferences for only a single choice set are elicited, the effects of between- and within-decision-maker variability are confounded. For example, if decision makers are asked to rank J options only once, it is not possible to identify separately the effects of ϵ_{ij} and μ_{ij} in [1]. Fortunately, with multiple choice sets or when choices are observed over time, it becomes possible to distinguish explicitly these sources of variability. In the context of time-dependent choices, parameter-driven dynamic approaches have proved useful to capture dependencies on the within- and between-person levels. For example, in the context of modeling voting data collected before and after the 1992 presidential election, Böckenholt (2002) applied the following vector-autoregressive model with

$$\boldsymbol{\mu}_{it} = \mathbf{Z}\boldsymbol{\mu}_{i,t-1} + \boldsymbol{\zeta}_{it} \qquad [4]$$

where $\boldsymbol{\mu}_{it}$ are the options' mean evaluations of person i at time t, and the $(J \times J)$ coefficient matrix $\mathbf{Z}$ contains the multivariate regression effects between the evaluations of the options at two adjacent time points. The diagonal elements of $\mathbf{Z}$ contain each option's autoregressive term and the off-diagonal elements contain the lagged effects of the $J-1$ remaining random utilities. The J-dimensional random effect $\boldsymbol{\zeta}_{it}$ captures the part of $\boldsymbol{\mu}_{it}$ that cannot be predicted on the basis of past evaluations of the options.

Social Dependencies

Aside from temporal dependencies, there is also strong interest in modeling proximity-based dependencies that are introduced by known or unknown (latent) relationships among individuals. This work goes beyond the standard assumption that individuals make choices in isolation by allowing explicitly for the possibility that choices of individuals are correlated or influenced by each other. Although it has long been recognized (Veblen, 1899) that choices of individuals may depend on their social network, empirical research on this topic has been slow, mainly because of methodological problems (Brock and Durlauf, 2001). Modeling issues that need to be addressed in empirical work on social interactions are (1) the identification of the reference group for which social-interaction effects are sought to be established, (2) self-selection processes of peer or group members, (3) controls for correlated effects that affect all group members in a similar way, and (4) controls for contextual effects such as exogenous social background characteristics of group members (Manski, 2007). Because these issues are difficult to tackle in any observational study, progress is most likely to be made by combining observational with quasiexperimental or laboratory studies.

Outlook

Parallel to this expansion of preference models, a growing literature has developed over the years that questions their

descriptive value. This work showed that the consideration of unsystematic error in [1] is insufficient to account for inconsistent choice behavior. May (1954) presented initial evidence that strategies for comparing alternatives can lead to systematic violations of such consistency criteria as weak stochastic transitivity, which is defined for the three options j, k, and l as

$$\Pr(j > k) \geq .50 \quad \Pr(k > l) \geq .50 \Rightarrow \Pr(j > l) \geq .50$$

More generally, in the same way as the meaning of a word is clarified by the context of the sentence in which it appears, the valuation of a choice option frequently seems to depend on the context of the choice set. The 'asymmetric dominance' and the 'compromise' effects are two well-known examples of systematic violations of expansion consistency (Simonson & Tversky, 1992). In the asymmetric dominance case, the dominance relation between two options affects their evaluations. This effect is not present when each of the options is presented in combination with an option that is neither dominating nor dominated. The compromise effect occurs when a two-attribute option is presented as falling between two extreme options that are strong on one attribute but weak on the other attribute. In this case, the 'compromise' option seems to receive a boost for having medium values on both attributes. Such relational effects cannot be captured by models that consider context-independent evaluations of choice options.

Many factors have been shown to affect decision processes. This list includes contextual effects (e.g., relational features such as dominance among choice options and temporal features of the choice situation), choice processes (e.g., the evaluability of options, decision strategies, and information search strategies), presentation formats, frames, cultural and social norms, as well as characteristics of the decision maker (e.g., emotional state, general intelligence, and numeracy). In view of this list, it is perhaps surprising how well the basic decomposition in [1] can work in providing satisfactory accounts of choice data.

Although experimental work has convincingly revealed the limitations of preference models based on Thurstone's (1927) framework, few would dispute their usefulness in rendering parsimonious descriptions of how individuals perceive and evaluate choice options. Many applications have shown that preference models can provide both a parsimonious quantitative description of choice outcomes and a flexible framework for modeling individual and contextual differences in choice behavior at a particular point in time or over time. Concurrently, there has been renewed interest in having foundational work on preference modeling go beyond the restrictive assumptions that utilities are predetermined, decomposable, and stable both across time and situations. Better measures and indicators of utility are being investigated that may prove useful to capture the hedonic experience associated with a choice outcome. For example, to infer utility from choices alone without taking into account anticipated or experienced hedonic reactions no longer seems sufficient (Kahneman, 2011). Measures of brain activity and brain electrochemistry in combination with experimental treatments provide much needed insights on the links between choice and sensations of pleasure and pain (Glimcher, 2011). Ways to relax the notion of utility maximization are also under investigation to take into account that the accuracy of perceptions is constrained by the information-processing capacity of one's nervous system.

Abstract

This article provides an overview of the field of Psychoneuroimmunology (PNI) which is a multidisciplinary field comprising the fields of psychology, immunology, and the neurosciences. The aim of PNI is to understand the bidirectional interrelationships between the mind, body, and disease. Therefore, PNI seeks to understand how stress and other psychological processes may impact upon nervous, endocrine, and immune system functioning. This article discusses the historical background of PNI, including key research findings as well as providing an overview of key psychological interventions used within this area.

Introduction

The field of psychoneuroimmunology (PNI) is the discipline that seeks to understand the complex interplay between the mind and body and how these connections may help explain the role of psychological processes in relation to health (Vedhara and Irwin, 2005). As such, PNI is inherently multidisciplinary in nature drawing predominantly upon the fields of psychology, immunology, and the neurosciences.

History

Two key figures regarded as the pioneers of PNI are Aaron Fredrick Rasmussen and George Solomon. In 1957, Aaron Fredrick Rasmussen and colleagues conducted a landmark study in which they demonstrated that mice that were put under stress were rendered more susceptible to the herpes simplex virus (Rasmussen et al., 1957). This, and a series of other studies, provided preliminary evidence that the brain may be capable of affecting the immune system. At the time this idea was considered with skepticism by the scientific community who largely believed that the central nervous system and immune systems were separate. Rasmussen's findings gained further credence from the work of George Solomon who also showed that psychological or environmental stressors may influence immunity (Solomon, 1969). In the ensuing years, Robert Ader and Nicholas Cohen were credited for advancing the field of PNI based upon a number of studies using animals, which further developed our understanding of how the brain may relate to the immune system. In one of their seminal experiments, Ader and Cohen (1975) gave rats varying volumes of a saccharin-laced water-based solution to drink while at the same time the rats were given Cytoxan, which is known to suppress the immune system and to cause unpleasant gastrointestinal symptoms. Ader and Cohen observed that the rats quickly began to avoid consuming the solution presumably because they had learned or had been conditioned to associate the solution with the unpleasant side effects. However, when they stopped giving the rats the drug, but continued to give them the saccharin-laced water alone, not only did the rats avoid drinking the solution, but some of the rats exhibited the same suppressed immune response shown previously. This finding was particularly interesting because the saccharin-laced water alone could not have been responsible for the impact the solution still appeared to have on the rats' immunity. Ader and Cohen reasoned that the rats had undergone a form of psychological conditioning and now maybe the brain was the mechanism by which the rats' immune systems were being suppressed.

These observations are regarded as playing a fundamental role in helping transform the way that we now think about the relationship between external stimuli, such as stressors, the brain, and the effect these factors can have on immunity. Robert Ader was later credited for coining the term 'psychoneuroimmunology.' A new era of science based upon understanding the role of the mind and body was born.

PNI and Stress

A key focus of PNI is the role that stress and other psychological processes may have on health through interactions between the nervous, endocrine, and immune systems. While many definitions exist, stress within this context is generally considered to be a cognitive process in which an individual subjectively appraises the demands of a situation, the resources they have to deal with the situation, and the resulting affective, behavioral and/or biological responses to this process (Cohen et al., 1995). Distress is thought to arise when the demands of a situation are believed to outweigh an individuals' subjective appraisal of their own ability to cope with the source of the stress i.e., the 'stressor,' which is typically characterized as chronic or acute. It is thought that the two forms of stress may impact upon the immune system differently. Chronic stressors are enduring major life stressors such as bereavement whereas acute stressors are shorter lived and include the everyday hassles that most of us are likely to encounter such performing a public-speaking task. It is believed that our default response to stress may serve an evolutionary role in that energy resources are mobilized when we perceive danger or threat.

The two main systems, which become activated in response to this process are the sympathetic–adrenal–medullary (SAM) system and the hypothalamus–pituitary–adrenal (HPA) axis. Activation of these systems results in increased secretion of stress hormones. The SAM system is activated by the autonomic

nervous system (ANS) and is characterized by the 'fight or flight' response of the sympathetic nervous system. The sympathetic branch of the ANS stimulates the release of norepinephrine, which results in elevated heart rate, blood pressure, and blood flow to essential organs. Several minutes later the HPA axis becomes activated resulting in the release of the stress hormone cortisol which, as well as other functions, plays a role in the regulation of immune responses. The release of stress hormones provides immediate physiological benefits when confronted with danger, such as fueling immediate energy release, yet it is rare that the daily demands that we encounter in the modern world always require this level of physiological output. The demands on an individual who is running away from a lion are quite different to the demands of bereavement, for example. Thus, while the stress response process is thought to serve important evolutionary functions, problems may arise when the SAM and HPA systems are chronically activated in response to relatively benign everyday situations. This is because chronic secretion of stress hormones are thought to cause changes to the distribution and activity of immune cells, which may well lead to poorer immune functioning (Vedhara and Irwin, 2005). The current understanding in PNI is that acute stress may enhance immune function whereas chronic stress may be detrimental to it.

A plethora of PNI studies have now shown that chronic or long-term emotional states such as long-lasting stress, anxiety, and depression are associated with alterations in immune functioning and worsened health outcomes for many conditions. Indeed, while the scope of PNI has broadened over the last 30 years, four main areas remain useful paradigms for exploring the role of emotional states in relation to health outcomes. The four main areas include wound healing, common cold studies, infections and vaccinations, and heart disease. These contexts allow psychoneuroimmunologists to examine the role of psychological processes and gain clinically relevant information on stress-related immune function and health. An overview of research and current understanding in each of these areas will now be considered.

Wound Healing

Wound healing provides a good model for investigating how psychological processes may impact upon immunity because the immune system is heavily involved at all stages of the wound repair process. Evidence for the role of stress on wound healing comes from both experimental and clinical studies. In a classic experimental study, Kiecolt-Glaser et al. (1995) demonstrated that wound healing took 24% longer in those individuals experiencing a form of everyday chronic stress. In this study, the researchers conducted a biopsy on the arms of 13 women who provided long-term care for an ailing relative and compared their healing rates to 13 aged matched controls who also underwent the biopsy procedure. The authors found that the carers took 9 days longer to heal compared to the age matched controls. These findings suggest that caregiving, a chronic stressor, may impair the early inflammatory response resulting in delayed wound healing. In a further study, Marucha et al. (1998) performed two biopsies on the hard palate within the mouths of 11 dental students. The first biopsy was conducted during vacation time and the second biopsy was performed 3 days prior to the students' examination period. Marucha et al. observed that the students took 40% longer to heal during their examination period, and none of students healed as rapidly during their examination period as they did during their vacation. In a similar study, Ebrecht et al. (2004) performed a 4 mm dermal biopsy on 24 healthy young men and monitored the men's healing rates 7, 14, and 21 days after the biopsy was performed using ultrasound scanning. Ebrecht et al. found that the slower healers exhibited significantly higher stress levels compared to those healing quicker.

Clinical studies also provide valuable insight and a number of studies have now been conducted, which suggest that stress, and other psychological factors, may impact upon the wound-healing process. Broadbent et al. (2003) assessed the effects of preoperative stress on postsurgical wound repair by assessing levels of stress before patients underwent a hernia operation. The authors found that higher stress levels predicted lower immune responses and greater worry about the operation predicted a more painful and slower recovery. Further, Doering et al. (2005) examined 72 patients undergoing coronary bypass surgery and found that higher stress-related symptoms at discharge predicted infection, impaired wound healing, and poor emotional and physical recovery. In fact, the authors found that the patients were 3.7 times more likely to experience wound infections and healing problems some 6 weeks after discharge.

Walburn et al. (2008) conducted a systematic review of published research in this area and found that stress was associated with healing rate across a range of wound contexts including acute and chronic forms of wounds within clinical and experimental studies. Taken together, evidence from both experimental and clinical studies combined suggest that stress and other psychological factors impact upon the wound-healing process. Other research in this field also highlight the importance of coping styles, positive affect, and the role of environmental factors such as social support in the healing process (Broadbent et al., 2012).

Common Cold Studies

We are all continually exposed to infectious agents, such as common cold viruses, yet only a proportion of us develop an infectious illness. Research conducted within this area suggest that stress may increase susceptibility to infectious illness. In a key study, Cohen et al. (1991) assessed the self-reported stress of 394 participants who rated their stress levels over the previous 12 months. Upon rating their stress levels, participants were then given one of five respiratory viruses, which were administered by the researchers using nasal drops. Cohen et al. found that the degree of stress the participants reported was related to the occurrence of infection in a dose-dependent manner. That is, the more life stress experienced over the previous 12 months the more likely the person was to become infected with the virus or suffer a cold. These findings were supported in a further study that found lower resistance to the common cold virus in participants reporting severe chronic stress for more than 1 month (Cohen et al., 1998).

Research examining naturally occurring viral infections also suggest that stress may be associated with an increased natural incidence of upper respiratory illness (Cohen et al., 2002).

Smolderen et al. (2007) investigated the stress levels, personality characteristics, and self-reported influenza-like symptoms in 5404 respondents from the general population and found that low mood and perceived stress were associated with increased reporting of influenza-like symptoms over a 4-week period. Further, Pederson et al. (2010) conducted a systematic review and meta-analysis of 27 published studies exploring the association between psychological stress and the risk of developing upper respiratory infection (URI). Overall, the findings of the review were that increased stress was associated with increased susceptibility to URI. Further research also suggest that these findings are independent of the age-related declines in immunity (Cohen et al., 2013).

Infections and Vaccinations

Vaccinations are commonly administered to prevent diseases such as influenza, hepatitis A and B, with the widespread use of vaccinations offering a useful paradigm for PNI research. Studies within PNI suggest that psychological factors may be important in determining how well an individual responds to a variety of vaccinations (Burns et al., 2003, 2002; Glaser et al., 2000; Jabaaij et al., 1993; Marsland et al., 2001; Phillips et al., 2005). Medical vaccinations, in particular hepatitis B and influenza, have received most of the attention to date. For example, psychological stress has been found to be inversely associated with the immune response to hepatitis B (Burns et al., 2002; Glaser et al., 1992; Jabaaij et al., 1993; Marsland et al., 2001). Results from other studies using the influenza vaccination have also found psychological stress to have negative consequences for immune responses in both younger (Burns et al., 2003; Phillips et al., 2005; Pressman et al., 2005) and older samples (Moynihan et al., 2004; Phillips et al., 2006). Responses to vaccinations have been found to be poorer in elderly individuals who provide long-term care for an unwell spouse compared with elderly non-caregivers (Kiecolt-Glaser et al., 1996; Vedhara et al., 1999; Wong et al., 2013). This is because providing care for an ailing spouse is regarded as a chronic form of life stress, which has both emotional and physical demands. This form of chronic stress may be particularly detrimental to the health of elderly individuals because of the underlying immunity impairments associated with aging. For example, no difference in vaccination response was observed between younger caregivers of multiple sclerosis patients compared to controls (Vedhara et al., 2002). This raises the issue of whether older caregivers, as a consequence of an aging immune system, are more susceptible to the effects of chronic stress. Alternatively, the findings could also reflect differences in caregiving experiences between caregiver populations. The findings of studies using younger populations have been mixed. The results suggest that general life stress may be associated with immune responses in younger populations (Burns et al., 2003; Phillips et al., 2005), whereas in older adults bereavement and nongeneral life events tended to be associated with impaired immunity (Phillips et al., 2006). Taken together, these studies suggest that psychological stress impacts upon immune responses, but that these factors may differ in salience across the life span.

A wide range of psychological factors such as an individual's perception of their social support and feelings of loneliness has also been found to affect vaccination responses. For example, feelings of loneliness and smaller social network size have been associated with lower antibody responses to influenza vaccination (Pressman et al., 2005). Students reporting lower social support produced poorer antibody response to pneumococcal vaccination whereas students reporting greater numbers of stressful life events also produced poorer responses to hepatitis A vaccination (Gallagher et al., 2008). Research also suggest that those individuals exhibiting a general feeling of elevated mood demonstrate more robust immune responses to vaccinations (Marsland et al., 2006) while those individuals exhibiting greater neuroticism have been found to produce weaker immune responses (Phillips et al., 2005).

Heart Disease

Several longitudinal studies have been conducted which suggest that stress may lead to a higher incidence of cardiac disease. For example, a longitudinal study over 14 years found that workers reporting higher chronic stress were more likely to develop risk factors for cardiovascular disease (Chandola et al., 2006). Further, a study of over 6000 men followed on average for almost 12 years showed that men reporting higher stress at the beginning of the study were more likely to develop coronary artery disease (Rosengren et al., 1991). Other studies in this area have compared cases of heart attack with control groups and demonstrated that higher stress (e.g., work, family, and financial) is associated with increased risk of myocardial infarction (Rosengren et al., 2004). Indeed, epidemiological studies suggest that stress and other psychological factors may contribute to the development of coronary artery disease while it is also recognized that factors such as personality characteristics and social isolation may also play an important mediator roles (Rozanski et al., 1999). More recently, Carroll et al. (2012) found that blood pressure reactions to a laboratory stressor were related to cardiovascular disease mortality 16 years later in a sample of 431 patients. These findings suggest that exaggerated cardiovascular responses in relation to acute stressful events may, if experienced frequently, impact upon long-term cardiovascular mortality. In a meta-analytic review, Steptoe and Kivimaki (2013) report that early life stressors, such as childhood abuse and early socioeconomic adversity, are linked to increased cardiovascular morbidity in adulthood. Further, the authors found an increased risk of coronary heart disease among adults experiencing job-related work stress and social isolation while stress, anger, and depressed mood may act as triggers of major cardiac events.

How Can Psychoneuroimmunology Be Used to Improve Health Outcomes?

While researchers have made remarkable progress in understanding the role of stress and other psychological factors on health, an important next step is to consider what interventions may be used to alleviate the adverse effects of

psychological functioning on immunity. One way that psychological interventions such as stress management, relaxation training, and emotional disclosure may confer benefits is by decreasing negative mood states and, therefore, reducing the associated nervous system, hormonal activation, and immune system functioning. Here we discuss some of the main interventions that have been used in PNI.

Emotional Disclosure

Emotional disclosure refers to acknowledging and discussing personal issues with attention placed on labeling the source of the problem and discussing its causes and consequences (Pennebaker, 1999). Research suggest that writing about important emotional issues for three to five consecutive days for 15–30 min each day may have an impact upon number of physician visits, immune responses, autonomic activity, as well as encourage improvements in overall mood (Pennebaker, 1999). An advantage of this technique is that a therapist does not need to be present as it is thought that the process of writing about one's feelings drives the reappraisal process. Indeed, writing about an issue may cause short-term distress but it is thought the long-term gains outweigh this effect (Booth, 2005). Petrie et al. (1995) showed that healthy medical students who wrote continuously for 20 min about emotional life events over a period of 4 days showed an enhanced antibody response to vaccination 4 and 6 months after the vaccination compared to a control group who wrote about unemotional life events only. Furthermore, research also suggest that emotional disclosure may impact upon wound healing. For example, Weinman et al. (2008) conducted a study in which 36 healthy participants were randomized to either an expressive writing group, which wrote about emotional events or a time management writing group. The two groups were given a punch biopsy 2 weeks later. Findings were that the wounds healed quicker in the emotional disclosure group. Several meta-analyses have also been published, which suggest that emotional disclosure, through the use of expressive writing may well be a cost-effective intervention which may be used to combat the influence of negative mood on health (Smyth, 1998; Frattaroli, 2006).

Cognitive Behavior Therapy and Psychotherapy

Cognitive behavioral interventions have been used in PNI in an attempt to alleviate stress and prevent the progression of disease by enhancing emotional well-being. A study by Antoni et al. (2000) found that a cognitive behavioral stress management (CBSM) intervention reduced anxiety, anger, and stress, and was associated with better immune responses in HIV-infected men compared with a control group. Cruess et al. (2000) found that a 10-week CBSM intervention provided positive immune benefits to HIV patients. Further, a study investigating 43 elderly caregivers demonstrated that a CBSM intervention, which included a weekly 1-hour counseling session delivered over 8 weeks was associated with enhanced antibody responses to influenza vaccination following the intervention (Vedhara et al., 2003). In other research, Antoni et al. (2009) conducted a study in which women breast cancer patients were randomized to receive either a 10-week CBSM intervention or a 1-day educational program 4–8 weeks after undergoing surgery. Those patients undergoing the CBSM intervention exhibited lower anxiety and better immune responses compared to controls.

A number of studies in this area have been conducted on the effects of psychological interventions on cancer survival. Spiegel et al. (1989) found that of 86 women diagnosed with breast cancer, those who participated in weekly expressive-supportive group therapy for 1 year survived 18 months longer over a 10-year period. However, the authors replicated this study some years later and found no statistically significant effect on survival time (Spiegel et al., 2007).Other research conducted in this area suggest that psychotherapy may well play a role in immune functioning and cancer survival. For example, Fawzy et al. (1993) evaluated the recurrence and survival of 69 patients diagnosed with malignant melanoma who had participated in a 6-week intervention, which involved education, coping, and stress management techniques. Fawzy et al. found that patients exhibited increased immune activity and survived for longer compared to those not receiving the intervention. However, evidence for the role of psychotherapy on cancer survival is currently mixed (Coyne et al., 2007).

Relaxation Techniques

The role that relaxation interventions may have on immunity responses has been investigated in a number of studies using nonpatient populations. For example, elderly individuals who engaged in muscle relaxation training for 1 month exhibited an improved immunity response to herpes simplex virus (Kiecolt-Glaser et al., 1985). Further, Irwin et al. (2003) observed improved immune responses in elderly individuals who underwent a 15-week tai chi program. Meditation, which is another form of mental relaxation has also been found to show positive effects on a number of immune and health outcomes. For example, a study of 48 healthy individuals found that those who attended an 8-week meditation course produced better immune responses in response to influenza vaccination and showed increased brain activity normally associated with positive emotion (Davidson et al., 2003). Nevertheless, while research using nonpatient populations are valuable, the use of clinical populations provides the most insightful and realistic information regarding the efficacy of relaxation techniques. Broadbent et al. (2012) examined the effects of relaxation on wound-healing processes in patients undergoing elective surgery. Participants were randomized to either receive standard care or standard care plus a relaxation intervention, which included guided imagery and take-home relaxation CDs that the patients listened to before and after undergoing surgery. Perceived stress before and after surgery was assessed using questionnaires. The authors found that those patients randomized to receive the relaxation intervention healed significantly quicker than the patients only receiving standard care. These findings provide preliminary evidence that a brief and relatively low-cost

relaxation intervention prior to surgery can reduce stress and improve the wound-healing process in a clinical population.

Conclusion

Since the early observations of Rasmussen in 1957, and the subsequent birth of psychoneuroimmunology some years later, PNI has provided almost unprecedented insight into the role of the mind in determining health outcomes. The multidisciplinary nature of PNI can be complex, and indeed present challenges; yet contributors to the field have been instrumental in breaking down multidisciplinary boundaries, which once restricted our understanding of the mind–body link. It is clear that PNI researchers have come a long way in demonstrating how stress and other psychological factors may impact upon health through interactions with the nervous, endocrine, and immune systems. In doing so, this has not only provided a sound evidence base but also improved our understanding of the psychological interventions and techniques, which may be used to alleviate the deleterious role of stress.

In future years, advances in the related fields of immunology and the neurosciences will likely prove promising as new methods of assessment and new ways of understanding immunity and disease are developed. Such advances will enable the field of PNI to further our understanding of how we as human beings function and how cognitions, emotions, and behaviors relate to health and well-being.

Psychopathy

Stuart F White and James R Blair, National Institute of Mental Health, National Institutes of Health, Bethesda, MD, USA

Abstract

Psychopathy is a developmental disorder associated with increased risk of instrumental and reactive aggression and with chronic and violent antisocial behavior in both youth and adults. Individuals with psychopathy show specific impairments in stimulus-reinforcement learning, emotional processing, and moral decision making. These deficits have been tied to dysfunctional amygdala response and to problems appropriately representing reinforcement expectancies in ventromedial prefrontal cortex. While treatment recommendations are currently sparse, recent work has shown that previous assessments of treatment amenability in this population may have been overly pessimistic.

Introduction

Psychopathy is a disorder that characterizes an individual showing pronounced emotional deficits and an increased risk for displaying antisocial behavior (Frick, 1995; Hare, 2003). The affective component of psychopathy, often called callous-unemotional (CU) traits, is the distinguishing feature of the disorder relative to other behavioral profiles associated with an increased likelihood of antisocial behavior (Blair, 2007). CU traits refer to a lack of guilt, remorse, and empathy (Frick et al., 2005). While it is past antisocial behavior that is particularly important in predicting future criminal activity (Walters, 2003), it is CU traits that are at the core of developmental trajectory associated with psychopathy (Frick and White, 2008). The disorder is developmental. It has been shown that CU traits in particular and the psychopathy more generally are relatively stable from childhood into adulthood (Lynam et al., 2007; Munoz and Frick, 2007). In addition, the functional impairments seen in adults with psychopathy (e.g., in responding to emotional expressions, aversive conditioning, passive avoidance learning, reversal learning, extinction) are also seen in adolescents with psychopathic tendencies (see later).

Several formal assessment tools for psychopathy exist, including the Antisocial Process Screening Device (Frick and Hare, 2001) and Psychopathy Checklist – Youth Version (Forth et al., 2007) for adolescents and the Psychopathy Checklist-Revised (Hare, 2003) for adults. Most research has identified three dimensions of behavior that compose psychopathy (Cooke et al., 2006; Frick et al., 2000; Neumann et al., 2006), though other models have been proposed (Cooke et al., 2006). These three dimensions are as follows: an affective factor that focuses on CU traits; an arrogant, deceitful, and narcissistic interpersonal style; and an impulsive, irresponsible, and antisocial behavior (Cooke et al., 2006; Frick et al., 2000; Neumann et al., 2006).

Psychopathy is not equivalent to the psychiatric conditions of conduct disorder (CD) or antisocial personality disorder (ASPD) as defined by DSM-5 or their ICD-10 counterparts. The diagnostic criteria for these disorders focus on antisocial behaviors rather than on etiological factors such as the emotion dysfunction seen in psychopathy (Blair et al., 2005). As such these psychiatric conditions describe individuals with difficulties in executive dysfunction (Moffitt, 1993), as well as individuals with symptoms stemming from CU traits. Consequently, individuals with psychopathy are a more homogenous group than those individuals meeting the criteria for CD and ASPD (Karnik et al., 2006). It should be noted, however, that DSM-5 includes the specifier for CD 'with limited pro-social emotions,' which stem directly from research on youth with CD and CU traits (Pardini et al., 2010; Pardini and Fite, 2010). Furthermore, the diagnosis of ASPD now includes components of psychopathy (APA, 2013). While the disorder of psychopathy will still not be equivalent to the DSM-5 diagnoses of CD and ASPD, there will be greater overlap in diagnostic conceptualization.

Psychopathy is characterized by an increased risk for antisocial behavior (Frick and Dickens, 2006; Hare, 2003). While several psychiatric disorders and neurological conditions, including CD and ASPD (APA, 2013), confer an increased risk of reactive aggression (Anderson et al., 1999; Leibenluft et al., 2003), psychopathy is unique in that it conveys increased risk for instrumental aggression (Frick et al., 2003). Furthermore, psychopathy is strongly predictive of institutional maladjustment and recidivism (Edens and Campbell, 2007; Walters, 2003), particularly violent recidivism (Edens et al., 2007; Hemphill et al., 1998).

Causes of Psychopathy

Genetic

Behavioral genetics work in children and adolescents (for a review, see Viding and McCrory, 2012) suggests that CU traits and psychopathy are highly heritable. Various twin studies across different groups have found the genetic influences account for between 40 and 78% of the variance in CU traits in the population (Viding and McCrory, 2012). Critically, in a large twin sample, antisocial behavior in youth high on CU traits was highly heritable ($h^2 = 0.81$), while antisocial behavior was much less heritable ($h^2 = 0.30$) in youth low on CU traits (Viding et al., 2005).

Despite the evidence suggesting that genetics plays an important etiological role in psychopathy, relatively little is known about the molecular genetics of the disorder. Studies in youth suggest that the long allele of the serotonin transporter

gene may be a risk factor for psychopathy (Sadeh et al., 2010, 2013). Additionally, Hirata et al. (2013) report an association between the single-nucleotide polymorphism rs6269 of catechol-*O*-methyltransferase and CU traits in a modest sample of antisocial youth. Though these early findings are promising, they are preliminary and further work is needed. Furthermore, it is quite possible that different genotypes are associated with the various deficits associated with psychopathy (see later).

Environmental

Relatedly, antisocial behavior in psychopaths and youth with CD and CU traits appears to be less influenced by environmental factors than antisocial behavior in youth with low levels of CU traits. Poor parenting is less associated with antisocial behavior in youth with high levels of CU traits (Hipwell et al., 2007; Oxford et al., 2003; Wootton et al., 1997; Yeh et al., 2011). Moreover, youth with CD and high levels of CU traits are less likely to have a history of trauma than youth with CD and low levels of CU traits (Kahn et al., 2013; Kimonis et al., 2012). Critically, despite the increased genetic influence and reduced environmental influence on the development of psychopathy and CD with high levels of CU traits, this does not mean that psychopathy is genetically determined (Viding and McCrory, 2012). In fact, there have been data to suggest that socioeconomic status plays a role in the expression of genetic risk for psychopathy (Sadeh et al., 2010), though the mechanisms of this gene by environment interaction are not understood.

Pathophysiology of Psychopathy

With respect to cognitive processing (including emotional processing) in psychopathy, the disorder is particularly interesting given the selectivity in the impairments seen. For example, executive functioning (Morgan and Lilienfield, 2000), theory of mind (Blair et al., 1996), and episodic memory (as long as it does not rely on augmentation by emotional content; Christianson et al., 1996) are intact in individuals with this disorder. There are, however, specific cognitive deficits in the processing of certain emotional expressions and in stimulus-reinforcement learning associated with psychopathy.

Empathy Impairment

Individuals with psychopathy show reduced autonomic responses to the pain and distress of others (Aniskiewicz, 1979; Blair et al., 1997; House and Milligan, 1976) and reduced recognition of emotional expressions (see Dawel et al., 2012; Marsh and Blair, 2008). Interestingly, this impairment in expression recognition is relatively selective. Recognition of fearful, sad, and happy expressions is reduced while the recognition of disgusted and angry expressions remains intact (Dawel et al., 2012; Marsh and Blair, 2008).

Decision-Making Impairment

Furthermore, psychopaths show impairment in stimulus-reinforcement learning. Psychopaths show reduced aversive conditioning; they are less likely to show autonomic activity to stimuli associated with shock (Rothemund et al., 2012). These individuals also show pronounced difficulties with reinforcement-based decision-making modalities including extinction (Newman et al., 1987), reversal learning (Budhani et al., 2006), economic decision making (Koenigs et al., 2010), and moral judgments (Aharoni et al., 2011; Blair, 1995; Blair et al., 1995; Koenigs et al., 2011; Young et al., 2012).

Moral Judgment Impairment

Individuals with psychopathy show specific deficits in certain kinds of moral judgments. It has been argued that different forms of norms are acquired and processed by at least partially dissociable systems. An early version of this position relates to the 'moral/conventional distinction'; the distinction between norms whose violation results in unjust/unfair treatment or in harmful consequences to others (harm/welfare-based; e.g., one person hitting another) as opposed to those whose violation challenges social conventions/norms (conventional; e.g., one person talking to another during class; Nucci and Nucci, 1982a,b; Smetana, 1995; Turiel, 1983). Psychopaths show impairment in distinguishing between harm/welfare-based and conventional norms (Blair, 1995). Individuals with psychopathy show reduced endorsement of harm/welfare-based norms (Aharoni et al., 2011; Glenn et al., 2009). They also show an increased likelihood to allow actions that indirectly harm another (Koenigs et al., 2011).

Neural Impairment

Structural Neuroimaging

There have been three relatively consistent structural MRI findings with respect to psychopathy. Psychopathy is associated with reduced amygdala volumes (Ermer et al., 2012; Fairchild et al., 2013, 2011; Huebner et al., 2008; Sterzer et al., 2007; Yang et al., 2010). Reduced ventromedial prefrontal cortex (vmPFC) has been seen in adults, though not consistently in youth (Ermer et al., 2012; Ly et al., 2012; Yang et al., 2009). Similarly, diffusion tensor-imaging studies have found reduced structural integrity of the uncinate fasciculus in adults, but not youth, with psychopathy relative to comparison individuals (Craig et al., 2009; Motzkin et al., 2011; Sundram et al., 2012). The uncinate fasciculus is a white matter tract providing extensive connection between the orbitofrontal cortex and the amygdala. Furthermore and again, only in adults, four studies have reported reductions in temporal pole (Ermer et al., 2012; Gregory et al., 2012; Ly et al., 2012; Yang et al., 2009), two in STS (de Oliveira-Souza et al., 2008; Yang et al., 2009), and three in orbitofrontal cortex (de Oliveira-Souza et al., 2008; Ermer et al., 2012; Yang et al., 2009).

Functional Neuroimaging

Findings in functional MRI studies (where IQ has been appropriately considered) have been relatively consistent for the amygdala. Individuals with psychopathy have been

reported to show amygdala activity during moral judgment (Glenn et al., 2008; Harenski et al., 2010). Additionally, a reduction in amygdala activity was seen in an emotional memory paradigm (Kiehl et al., 2001). In youth with psychopathic traits, reduced amygdala response to fear/distress in others has been found consistently (Carre et al., 2012; Jones et al., 2009; Marsh et al., 2008; Viding et al., 2012; White et al., 2012). In adults, this finding has been less consistent. Violent schizophrenic patients with psychopathy show reduced amygdala responses to fearful expressions (Dolan and Fullam, 2009) – though a relationship between psychopathic traits in aggressive individuals and amygdala responsiveness to fear/distress expressions was not seen in another study (Pardini and Phillips, 2010).

Reduced vmPFC and caudate activation to reward has been seen in youth with psychopathic traits (Finger et al., 2011), though findings in adults have been inconsistent (Bjork et al., 2012; Buckholtz et al., 2010; Pujara et al., 2013). Importantly, recent neuroimaging work suggests that the reduced response to reward in vmPFC and caudate is associated with antisocial behavior generally and is not specific to psychopathy (Crowley et al., 2010; Rubia et al., 2009; White et al., 2013b). It is important to emphasize that while vmPFC and caudate dysfunction may not be specific to psychopathy, deficits in these regions have been observed in psychopathy and particularly vmPFC dysfunction in psychopathy is well documented (Blair, 2007).

Development of Psychopathy

As noted earlier, psychopathy is associated with deficits in emotional responses (particularly to fear/distress in others), impaired decision making, and problems making moral judgments. These deficits stem directly from neural impairments observed in both the structural and functional neuroimaging work. The amygdala is a key structure in stimulus-reinforcement learning (Everitt et al., 2003). In other words, the amygdala is necessary to learn the 'goodness' and 'badness,' or reinforcement value, of actions, objects, or events. In humans and other primates, fear/distress in conspecifics serves as a negative reinforcer, which is learned, via the amygdala, to be avoided (Hooker et al., 2006; Mineka and Zinbarg, 2006). Individuals with psychopathy fail to represent the fear/distress of others as aversive due to amygdala dysfunction (Sylvers et al., 2011; White et al., 2012). Furthermore, the amygdala projects forward into vmPFC, supplying important information regarding the valence of reinforcement expectations for use in decision making (Blair et al., 2006). As the amygdala is dysfunctional in psychopathy, inappropriate reinforcement expectation information is likely passed forward for use in decision making (Blair, 2007).

These deficits come together to predispose individuals with psychopathy to antisocial behavior (Blair, 2007). Deficits in harm/welfare-based norm processing make it more difficult for psychopaths to distinguish between prosocial and antisocial behavior. Deficits in representing the fear/distress of others as aversive make it much easier for psychopaths to engage in instrumental aggression. Finally, the decision-making deficits seen in psychopathy will likely increase the exposure to frustration. As humans exposed to frustration are more likely to reactively aggress (Berkowitz, 1993), psychopaths are also at increased risk of reactive aggression (Blair, 2010).

Treatment of Psychopathy

Initial examinations of treatment amenability in psychopathy were relatively negative. A number of investigations found that both adults (Ogloff et al., 1990) and youth with psychopathy (Falkenbach et al., 2003; Gretton et al. 2001; Hawes et al., 2013; O'Neill et al., 2003; Spain et al., 2004) showed worse response to treatment than other antisocial individuals. More recent work, however, has begun to examine factors underpinning differential treatment response in psychopathy (Hawes and Dadds, 2005) and suggests that previous pessimism regarding psychopathy and treatment response may have been overstated (Caldwell et al., 2006; Hawes and Dadds, 2005; Kolko and Pardini, 2010; White et al., 2013).

Summary

Psychopathy is a developmental disorder associated with increased risk of both instrumental and reactive aggression. The disorder is associated with chronic and violent antisocial behavior in both youth and adults. Individuals with psychopathy show specific impairments in stimulus-reinforcement learning, emotional processing, and moral decision making. These deficits have been tied to dysfunctional amygdala response and to problems appropriately representing reinforcement expectancies in vmPFC. While treatment recommendations are currently sparse, recent work has shown that previous assessments of treatment amenability in this population may have been overly pessimistic.

Abstract

Treatment with drugs is an important aspect of the therapeutic interaction and management in all medical conditions including psychiatric disorders. Many psychiatric disorders take on a chronic, long-term course which produce significant economic impact on the individual as well as the society. It is important for clinicians to be aware of the economic aspects of drug prescription. With increasing longevity there is every likelihood of co-morbidity which will lead to increased burden. In various health care systems thus there is also likely to be a competition for increased resources. In order to avoid arbitrariness clinical guidelines can enable and support the clinicians but it is also important that resource allocation is made on a scientific basis which has been established by pharmacoeconomics. Development of atypical neuroleptics, selective antidepressants and acetylcholinesterase inhibitors has produced major additions to psychopharmacotherapy. It is important that clinicians and policymakers alike are aware of economic costs and aspects of medications being prescribed and the cost–benefit ratio.

Introduction

Psychopharmacotherapy is one of the mainstays of the treatment of psychiatric disorders. These are highly prevalent and frequently take a chronic or chronic remittent course, thus having a high economic impact. Whereas the demand for medical services is increasing, the growth of the resources allocated to health care is increasingly restricted. Thus, diseases and the patients suffering from them compete for the resources. In order to avoid arbitrariness, resource allocation needs a scientific basis which has been established by pharmacoeconomics. Major breakthroughs have been achieved in psychopharmacotherapy particularly by the introduction of atypical neuroleptics, selective antidepressants, and acetylcholinesterase inhibitors. Although there is a need for more research, the pharmacoeconomic analyses available suggest that the new drugs may at least be cost neutral or even cost saving despite their higher acquisition costs, essentially by reducing institutionalization. Nevertheless, the access of patients to the new therapeutic chances is restricted on economic grounds although this varies internationally.

Psychopharmacotherapy is one of the mainstays of the treatment of psychiatric disorders besides social therapy and psychotherapy. Psychiatric disorders essentially comprise the affective disorders (depression, bipolar, i.e., manic-depressive disorder), the schizophrenias, the anxiety disorders (panic disorder, generalized anxiety, post-traumatic stress disorder, obsessive–compulsive disorder, social phobia), the eating disorders (bulimia and anorexia nervosa), the substance abuse and dependence disorders including alcoholism, the personality disorders, and the dementias (with Alzheimer-type dementia being the cause in about 70% of cases). They are highly prevalent (Table 1) and frequently take a chronic or chronic remittent course. Therefore, it is easily understandable that the total costs of psychiatric disorders compare very well with the costs of the leading somatic illnesses (Table 2). The prevalences of depression and of the eating disorders are increasing. The WHO burden of illness study (Murray and Lopez, 1997) suggests that depression will be the leading

cause of disability in the developed countries in 2020. Psychiatric disorders (except the dementias) manifest in early adulthood, thus limiting the abilities of patients for social achievement.

Psychopharmacotherapy essentially comprises seven classes of drugs:

1. neuroleptics for the treatment of psychotic states, especially the schizophrenias;
2. antidepressants for the treatment of depression of whatever origin as well as for the long-term treatment of anxiety disorders;
3. mood stabilizers (lithium, some anticonvulsants) for the short-term treatment of mania and for the long-term relapse and recurrence prevention of affective disorders;
4. minor tranquilizers (essentially benzodiazepines) for the short-term treatment of anxiety and agitation of whatever origin and of alcohol withdrawal syndromes;
5. hypnotics (essentially benzodiazepines and benzodiazepine-like drugs) for short-term treatment of insomnia;
6. anticraving compounds (bupropion for smoking cessation, acamprosate for alcohol abstinence, opiate antagonists for alcoholism and opiate dependence) which, however, are not yet approved in all countries; and
7. cognition enhancers (nootropics such as piracetam, ginkgo biloba) for the nonspecific treatment of dementias and acetylcholinesterase inhibitors specifically for Alzheimer-type dementia.

Concerning the eating disorders, only one drug, the antidepressant fluoxetine, is approved for supportive treatment of bulimia.

Psychopharmacotherapy competes with psychotherapy in the treatment of mild to moderate depression and the anxiety disorders. The relative merits of both alternatives are subject to debate which is fueled by a lack of scientific data, ideology, and economic interests of the health care providers involved. As a rule of thumb, pharmacotherapy and psychotherapy may be thought not to be alternatives but supplements whenever a psychiatric disorder is moderate to severe, although a synergistic action remains to be definitely proved.

Life expectancy increased dramatically in the twentieth century, and this was accompanied by an increase in the prevalence of age-associated diseases. In the field of psychiatry these are the dementias. Thus, although the number of healthy life years is generally increasing, the prevalence of chronic diseases is increasing in parallel. Consequently, the demand for health care services is increasing. Costs for drug therapy are increasing overproportionately because drug development has become increasingly complicated and costly. The mean investment necessary for developing a single new chemical entity to approval amounts to about US$500 million.

Worldwide, health care is one of the most rapidly growing markets with positive impacts on employment. Nevertheless, governments internationally tend to restrict the growth because at least part of it is publicly funded. The fundamental but unanswered question is what proportion of the gross domestic product society is willing to invest in health care. Obviously, however, most people value health and thus health care very highly. Thus, disorders, i.e., the patients suffering from them, compete for limited resources. Economic criteria have become a third dimension besides efficacy and effectiveness as well as tolerability and safety when selecting between treatment options. It is easily conceivable that psychiatric disorders, faced with persistent stigma, have a hard standing in this competition.

Pharmacoeconomics, a young scientific discipline, has developed a sound scientific basis for the evaluation of the economic dimension (Gold et al., 1996). This is indispensable in the interests of an ethically justifiable allocation of resources. The question is whether a new, more costly drug allows one to achieve better outcomes so that it is worth its higher costs. In principle, a new drug might even spare money in that the better outcome might help avoid costly, higher-level health care such as inpatient treatment and reduce indirect costs, e.g., by less absenteeism.

Basic Terms of Pharmacoeconomics

Pharmacoeconomics is the science of measuring *costs* and *outcomes* associated with the use of pharmaceuticals in health-care delivery. Its objective is to improve public health through rational decision making when selecting among alternative therapies, e.g., for formularies and their impact on costs and outcomes. Several methodological guidelines have been published (e.g., CCOHTA, 1994).

Outcomes are the possible end result of a particular treatment. Outcomes depend on the *effectiveness* of the treatment under the influence of all the confounding variables in real life. Therefore, costs have to be measured under real-life conditions. In contrast, the experimental *efficacy* trials are designed to eliminate as completely as possible all confounding influences. The outcome parameter chosen should have high everyday relevance, e.g., the rate of full remissions of depression.

Costs are the resources consumed by the illness and by its treatment. *Direct costs* are those directly related to treatment such as prescribed medication, self-medication, consulting the physician, blood tests, transportation, psychotherapy, occupational therapy, informal care by relatives, etc., as well as costs for hospital and nursing-home treatment. *Direct costs* include those for diagnosis and treatment of side effects and complications of the initial therapy. There is methodological controversy as to whether the costs of social support (welfare, unemployment benefit, disability pension, housing benefit, etc.) should be included in the direct costs. A complete evaluation of direct costs should consider the opportunity costs, i.e., the lost potential of the resources invested to provide more efficient benefits in other fields.

Indirect or *future costs* are those related to lost productivity due to illness, i.e., due to absenteeism, premature pensioning because of disability, and premature death (e.g., by suicide) as well as those related to health care consumption during the years of life gained owing to the intervention. Concerning psychiatric disorders, costs of violence and crime also have to be considered. *Intangible costs* comprise those attributable to impairments of the quality of life, e.g., of the patients themselves and their relatives and acquaintances involved in the care.

The economic impact of treatment extends into the future. If costs and benefits accrue during different periods, costs and

savings have to be discounted for the remaining life span of the patient sample in question. Discount rates are supposed to reflect the rates of return on private-sector investments and are generally set at 3–5%.

If the costs are low and the outcomes excellent the decision in favor of the treatment is obvious as is its rejection if the costs for poor outcomes are high. Therefore, pharmacoeconomic analyses make sense only when both the costs and the quality of treatment are high or low. The economic *efficiency* then is the ratio of costs divided by the outcomes. When allocating resources the drug yielding the most favorable outcomes at the lowest cost will be favored.

Types of Pharmacoeconomic Analysis

The basic requirement of a pharmacoeconomic analysis is the definition of the perspective, e.g., that of the patient, the health care provider, the health insurance as the payer, or the societal perspective of government. The categories of costs to be considered depend on this perspective. For example, from a provider's perspective, the value of an antidepressant drug under capitation may be expressed in terms of cost per reduction in some depression scale score. From the patient's perspective, the value may be in cost per full treatment response with least side effects. From the societal perspective, the value may be in cost per patient returning to continuous employment at or above the level of previous education. Simply to compare the daily costs of medication does not fulfill the criteria of pharmacoeconomic analysis.

The principle types of analysis include cost-minimization analysis, cost-effectiveness analysis, cost-utility analysis and cost–benefit analysis. *Cost-minimization* analysis assumes that the interventions in question yield identical outcomes; this is rarely valid. *Cost-effectiveness* analysis compares the costs of alternative treatments in terms of a specific health outcome such as life-years gained, e.g., by reducing mortality from suicide, or responder rates. *Cost-utility* analysis (CUA) adjusts the life-years gained by some measure for quality of life. Thus, the results of CUA are typically expressed as costs per quality adjusted life years (QALYs). Quality of life is assessed either by some rating scale for health-related quality of life or, more typically, by determining the preferences of patients suffering from specific diseases for one or the other disease state as opposed to perfect health where perfect health is set as '1' and death as '0.' In *cost–benefit* analysis, the QALYs gained are transformed into monetary terms using the human capital approach or willingness-to-pay approach.

As there is no one-to-one relationship between therapeutic intervention and outcome and its financial sequelae, the impact of these uncertainties has to be estimated. This is done by *sensitivity analysis*, where key variables are systematically modified and the economic consequences calculated yielding best- versus worst-case scenarios.

Pharmacoeconomic Study Designs

There are two principle approaches to pharmacoeconomic analysis: the clinical trial approach (experimental or observational), and the modeling or systems approach. The former means gathering cost data (retrospectively or, preferably, prospectively) in clinical trials. The latter '*in vitro*' approach applies decision-tree analysis to data available from published literature and databases.

Current guidelines favor the clinical trial approach as the 'gold standard.' Modeling, however, can overcome limitations implicit in clinical trials. These include the selection bias concerning the patients recruited in randomized, strictly controlled, and therefore artificial efficacy trials, thus limiting generalizability. Furthermore, their observation period rarely exceeds a few months whereas economic consequences may extend far into the future. Efficacy trials necessarily are underpowered for economic analysis because sample size estimation is based on the critical difference and variability of the efficacy parameter. Obviously, the critical difference and variability of economic data will fundamentally differ. Clinical trials using the mirror image design, i.e., comparing costs and benefits in a defined period before and after administering a specific drug, are of limited value because at least in psychiatric disorders there is a spontaneous decrease of the costs per outcome during the course of illness irrespective of the mode of treatment.

The putatively best experimental design is a prospective, randomized, 'naturalistic,' i.e., non-blind, adequately powered clinical trial. Both principle approaches, the clinical trial approach and modeling, have their weaknesses and strengths so that they are not really exclusive alternatives but complementary.

Friedberg et al. (1999) found that studies sponsored by drug companies were less likely to report unfavorable results than studies funded by nonprofit organizations. This finding could be due to various sources of bias which, however, if present, still have to be identified.

The organization of health-care supply, the health-care utilization patterns, and the prices differ considerably between and even within cultures. Therefore, the results of pharmacoeconomic analyses cannot simply be transferred from one health care market to another.

Pharmacoeconomic Findings with Neuroleptics

Since the 1990s new neuroleptics have been introduced (amisulpride, clozapine, olanzapine, quetiapine, risperidone, sertindole, zotepine), although not yet approved in all countries. These compounds are called 'atypical' because they have a lower incidence of extrapyramidal side effects (e.g., Parkinsonism) than conventional neuroleptics (e.g., haloperidol, fluphenazine). Moreover, they possibly have superior efficacy concerning cognitive dysfunction and so-called negative symptoms as well as quality of life in schizophrenia. These advantages might improve compliance, which is most important in long-term relapse and recurrence prevention. The costs of daily treatment with atypical neuroleptics exceed those of conventional neuroleptics by a factor of 2–8 depending on the compound and the country considered. On the other hand, neuroleptic medication costs generally make only about 4–8% of direct costs.

The pharmacoeconomic analyses actually available for neuroleptics are limited to amisulpride, clozapine, olanzapine,

risperidone, and sertindole in schizophrenia. The majority of studies address clozapine, olanzapine, and risperidone. The costs are mostly considered from the payer's perspective, i.e., addressing direct costs. Most are cost-effectiveness analyses, some cost-utility analyses. The majority follow the modeling approach. The economic analyses based on clinical efficacy trials have the limitations discussed above, especially those restricting the analysis to study completers. This is far from the naturalistic, real-world approach necessary. There is only one randomized, naturalistic, adequately powered trial comparing clozapine with conventional neuroleptics, where clozapine significantly reduced the frequency and duration of inpatient treatment; the cost data are to be reported. All in all, the current evidence suggests that clozapine is cost-effective for neuroleptic-refractory schizophrenia and that olanzapine and risperidone therapy may be cost-neutral despite higher medication costs (Revicki, 1999). Nevertheless, the access of patients to the new therapeutic chances is restricted on economic grounds, although this varies internationally.

Pharmacoeconomic Findings with Antidepressants

Since the 1980s, a number of new antidepressants have been introduced (selective serotonin reuptake inhibitors (SSRI): citalopram, fluoxetine, fluvoxamine, paroxetine, sertraline; the selective norepinephrine reuptake inhibitor reboxetine; the serotonin–norepinephrine reuptake inhibitor venlafaxine; the norepinephrine auto- and heteroreceptor blocker mirtazapine; the reversible and selective inhibitor of monoamine oxidase moclobemide), although not yet approved in all countries. Their efficacy is comparable to that of traditional tricyclic antidepressants (TCAs such as amitriptyline, imipramine, desipramine, nortriptyline), but owing to selectivity their tolerability and safety are superior. Safety is of specific concern in view of the suicide risk, although antidepressants are involved only in the minority (<10%) of suicides. These advantages help reduce drop-out rates although to a limited degree (about 25% versus 29%). Nevertheless, this might be particularly relevant in long-term recurrence prevention which is necessary in about 60% of patients in whom antidepressants are indicated. There is a dramatic underrecognition and undertreatment worldwide (Davidson et al., 1999; Tylee et al., 1999). Undertreatment causes a doubling of direct costs due to increased utilization of other medical services (Manning and Wells, 1995) and increases indirect costs due to absenteeism. The advantages of innovative antidepressants might increase acceptability and thus utilization of antidepressants. The costs of daily treatment with selective antidepressants, however, exceed those of TCAs by a factor of 2–20 depending on the compound and the country considered. On the other hand, antidepressant medication costs generally constitute only about 3–6% of direct costs.

Pharmacoeconomic analyses published cover all innovative antidepressants except reboxetine. All but one (Gould et al., 1995) are restricted to depression. The costs are mostly considered from the payer's perspective. Most are cost-effectiveness analyses, only a few cost-utility and cost–benefit analyses. There are no randomized, open-label, naturalistic, adequately powered trials but some studies analyzed large, complete samples of HMO participants. By far the majority follow the modeling approach. There are some outstanding analyses in which classes of compounds are compared (e.g., CCOHTA, 1997; Casciano et al., 2000). Overall, the current evidence suggests that extended-release venlafaxine might be more cost-effective than SSRIs and that the cost-effectiveness of SSRIs might equal or even exceed that of TCAs, despite higher medication costs (Conner et al., 1999; Casciano et al., 2000). However, more research is needed before this can be taken for granted. Accordingly, there is debate as to whether the access of patients to innovative antidepressants should be restricted or whether they should be recommended as first-choice drugs (CCOHTA, 1997).

The limited evidence available suggests that psychotherapy is more likely to be cost-effective the more severely afflicted the patients are (Gabbard et al., 1997). The cost of psychotherapy is about 3–6 times higher than that of antidepressant drug therapy. One modeling study (Antonuccio et al., 1997) suggests, however, that cognitive behavioral therapy (CBT) might be more cost-efficient than fluoxetine treatment of depression owing to lower recurrence rates after psychotherapy. In a CUA based on a randomized controlled trial (Lave et al., 1998), nortriptyline was slightly superior to interpersonal psychotherapy. One meta-analysis (Gould et al., 1995) suggests that CBT is superior to imipramine and cost-effective in panic disorder. Economic analyses addressing the relative merits of pharmacotherapy and psychotherapy are completely lacking for prominent diseases such as obsessive–compulsive disorder, generalized anxiety, and social phobia.

Pharmacoeconomic Findings with Mood Stabilizers

Mood stabilizers by definition reduce the risk of relapses and recurrences and thus putatively hospitalization. Therefore, they may be expected to reduce direct costs (about 60% for hospitalization). Lithium is the only drug reducing mortality essentially by reducing the suicide rate (Ahrens, 1997). Only a few pharmacoeconomic analyses have been published. Lithium was more cost-effective than carbamazepine from the payer's perspective in a modeling approach based on retrospectively gathered data from a randomized controlled clinical trial (Dardennes et al., 1999). Valproate was more cost-effective than lithium over 1 year from the payer's perspective in a modeling approach (Keck et al., 1996); the prophylactic efficacy of valproate, however, remains to be established.

Pharmacoeconomic Findings with Tranquilizers and Hypnotics

There are almost no economic analyses published on tranquilizers or hypnotics. Yuen et al. (1997) found that hospital stay was longer and costs were higher in elderly people if sedative–hypnotic medications were prescribed, even if prescription adhered to established guidelines. Research is needed especially to clarify whether the higher costs of the newer hypnotics (zaleplon, zolpidem, zopiclone) compared with benzodiazepines are economically justified.

Pharmacoeconomic Findings with Anticraving Drugs

Long-term acamprosate adjunctive to conventional therapy was found to be cost-effective in the treatment of alcoholism in the German setting in a single, retrospective modeling study (Schädlich and Brecht, 1998). Opiate antagonists (Howard et al., 1996), opiate agonist (methadone) substitution, and bupropion have not been evaluated economically.

Pharmacoeconomic Findings with Cognitive Enhancers

There are no economic analyses published on nootropics. The acetylcholinesterase inhibitors donepezil (Foster and Plosker, 1999) and rivastigmine (Fenn and Gray, 1999) seem to be at least cost-neutral, especially by delaying the need for institutionalization. The current evidence is restricted, however, to a few observational studies and modeling analyses using the cost-effectiveness approach from the payer's perspective. Economic analyses on galanthamine, an acetylcholinesterase inhibitor and nicotinic agonist expected to be approved, remain to be published.

Conclusions and Some Precautions

The innovative neuroleptics and antidepressants not only have the potential for a balance of costs despite higher costs of medication, but might even save direct costs essentially by reducing the risk of institutionalization owing to lower drop-out rates in comparison with traditional compounds. This conclusion, however, is based essentially on decision analyses, i.e., modeling. More research, particularly large-scale, randomized trials under naturalistic conditions, is needed. From a systemic perspective, the potential cost savings can only be realized if the institutions concerned, e.g., hospitals, reduce their capacities accordingly. About 80% of the costs of hospitals are common costs, mostly wages and salaries. Whereas in a free health-care market the savings might be realized by market forces, in systems bound in economic welfare a political will is needed to enforce the inevitable dismissal of staff.

Abstract

In parallel to advances in neuroscience, more treatment options for psychiatric disorders have become available. Since the original preparation of this article, for example, atypical antipsychotics have been in wide use for the treatment of psychotic, even for mood symptoms. Significant challenges remain though, as atypical antipsychotics are associated with side effects that continue to negatively impact the medical health of majority of patients. Special patient populations such as children and the elderly can be more vulnerable to side effects. In this article, we have included subsections for these populations with further references so that more detailed information can be gathered by the interested reader. This article is written with an intention to educate all clinicians, including those in training, involved in the care of psychiatric patients. Because comprehensive care includes several disciplines addressing the different needs of patients consistent with a psychosocial model, it is imperative for not only patients, but also support staff to be knowledgeable of these basic facts. As detailed in the article, side effects can often mimic underlying pathology and easily be confused the actual symptoms of the illness. Therefore, a sound knowledge base, careful assessment and vigilance are necessary for the assessment of side effects of psychoactive medications. For the psychiatrist in clinical practice, frequent monitoring of side effects is critical. In addition, development of psychoactive medications with favorable side-effect profile needs to be priority for the industry.

Psychopharmacology studies drug-induced alterations in the cognitive function and behavior of humans and aims to develop treatment strategies for neurological and psychiatric disorders. Like all drugs, psychoactive drugs are associated with side effects (adverse effects) which may be generated both centrally and peripherally. The spectrum of drug effects originates largely from their effects on multiple neurotransmitter systems, and the interactions of these systems with each other and other sites of action in the central nervous system. One of the strongest predictors of treatment noncompliance is early onset and persistence of side effects. The strongest determinant of the interindividual variation in the experience of side effects is believed to be in the genetic make up. The study of pharmacogenetics targets drug development that will be both efficacious and well tolerated for each individual. Management of side effects includes a baseline assessment, careful choice of medication, patient and family education, minimization of the number of drugs (to decrease potential side effects and to avoid drug interactions), single bedtime dosing, the availability of clinicians for frequent monitoring, adjustment in dosage, counteractive drug treatment, and continuous assessment. In this article, major behavioral side effects of psychoactive drugs such as sedative, cognitive, and motor effects are examined. These factors play a critical role in the quality of life of patients.

Psychopharmacotherapy refers to the treatment implications of the science of psychopharmacology. Psychopharmacology is the study of drug-induced alterations in the cognitive function and behavior of humans that aims to develop treatment strategies for neurological and psychiatric disorders. Rapid technological progress has led to an abundance of scientific techniques in neurochemical and animal studies on the interaction between drug action and behavior (Feldman et al., 1997).

Most psychoactive drugs exert their effects first by interfering with the communication between nerve cells (neurons). At the molecular level this occurs by their interaction with receptors of neurotransmitters located on the surface or inside the neuron. This step initiates a cascade of events that eventually leads to alterations in the neurotransmitter and/or hormonal systems. Nonspecific drug action at any level in this process results in side effects. The term side effect implies an undesirable (adverse) drug effect; a particular side effect of a drug for a given condition may be a desirable one for another condition. For instance, benzodiazepines may be prescribed for anxiety disorders, but as a side effect they cause sedation. On the other hand, they may also be prescribed for the treatment of insomnia as a primary indication. Indeed, the psychoactive potential of several drugs was discovered as a result of unexpected but beneficial side effects in psychiatric patients who were taking these drugs for other therapies (see below). The spectrum of drug effects originates largely from their effects on multiple neurotransmitter systems, and the interactions of these systems with each other and other sites of action in the central nervous system.

At times it is a challenge in the practice of psychiatry to be able to determine if a given behavior is a symptom of an illness or a side effect of drug treatment, as the latter may mimic the former. For instance, untreated patients with schizophrenia frequently display decreased spontaneity, lack of motivation, and social isolation. These symptoms resemble some of the extrapyramidal system (EPS) side effects induced by conventional antipsychotics. A practical management of this potential difficulty involves careful assessments of the patient's functions e.g., sleep patterns, daily living routines, and sexual function prior to treatment.

Historical Perspective

Treatment with substances that alter mood, thinking, and cognition date back to prehistoric times (Spiegel, 1996).

Various psychoactive substances have been used in religious ceremonies, rituals, and for healing of pain.

Alcohol is the oldest drug used for its calming and sedative effects. The disinhibition caused by alcohol is described in the first book of the Old Testament. Apart from consumption in social settings, alcohol was introduced for medical use in the nineteenth century as a general anesthetic. The narrow therapeutic index (the ratio of toxic over desired dose) of alcohol limited its usefulness for this purpose.

Opium (*papaver somniferum*), *hellebore*, and *rauwolfia* roots are among the oldest compounds that were extracted from plants in prehistoric and ancient times. Morphine was isolated from opium in the beginning of the nineteenth century and has been available as an analgesic with considerable addiction potential.

In ancient times, different forms of hellebore root were used as emetics, laxatives, and for mental conditions such as mania and melancholy. Risk of seizures limited its use. *Rauwolfia serpentina* roots were used by Indians to treat snake bites and also in some mental conditions. Reserpine, a rauvolfia alkaloid was noted to have a calming effect in patients with schizophrenia. Because reserpine induces severe depression as a side effect, its use as an antipsychotic has been abandoned.

Cocaine is an alkaloid derived from the shrub *Erythroxylon coca*; it originated in South America where it was used for its stimulating effects. It was isolated in the nineteenth century and is still used as a local anesthetic. Paranoid delusions, hallucinations, seizures, and dependency are some of the adverse effects of systemic cocaine use.

The discovery of psychoactive medications has resulted from the side-effect profiles of drugs used in medicine. For instance, the antipsychotic chlorpromazine was initially used to help patients with presurgical preparation and as an adjuvant to anesthetics. Its sedative and calming effects easily found its way to treatment in psychiatric disorders as a primary indication soon after its antipsychotic properties were discovered. Similarly, iproniazid (an antidepressant of the monoamine oxidase inhibitor – MAOI type) was originally developed as a drug for the treatment of tuberculosis. In clinical drug trials, patients treated with this drug were observed to become stimulated and cheerful. This observation led to the investigation of the antidepressant effect of iproniazid.

Genetic Factors and Side-Effect Vulnerability

Side effects are not uniformly observed in everyone. While some patients never develop a certain side effect, others are affected from day one of treatment. The strongest determinant of this interindividual variation is believed to be in the genetic complexion. Variations in the sequence of the DNA called polymorphisms are believed to play a role in expression of a wide spectrum of reactions to drugs: from full response to nonresponse; minimal to severe side effects. The completion of the Human Genome Project may aid in the identification of patient subgroups according to their drug response patterns. For instance, certain variations in the gene that codes for the enzyme CYP2D6 lead to slow metabolism of some drugs such as tricyclic antidepressants, therefore these patients run higher levels of drugs and are more vulnerable to side effects (Schatzberg and Nemeroff, 1998). The application of pharmacogenetics will be the identification of drugs that will be both efficacious and well tolerated for each individual according to his or her genetic makeup.

Assessment and Management of Side Effects

As compared with the rating scales used to assess the symptoms of diseases, there are relatively few rating scales for the assessment of side effects. The most comprehensive of these is the Systematic Assessment for Treatment Emergent Events which has been designed for use in clinical drug trials. Udvalg for Kliniske Undersogelser Side-effect Rating Scale is also comprehensive and was developed for use in clinical trials and in routine practice. The Rating Scale for Extrapyramidal Side Effects (Simpson–Angus Extrapyramidal System Scale), Barnes Akathisia Rating Scale, and Abnormal Involuntary Movement Scale were developed to measure the EPS side effects, akathisia, and dyskinetic movements, respectively, that are associated with antipsychotic drug use (American Psychiatric Association, 2000). Even though each side effect ultimately requires individual management, a comprehensive approach is vital for general management. Such an approach involves a baseline assessment, careful choice of medication, patient and family education, minimization of the number of drugs (to decrease potential side effects and to avoid drug interactions), single bedtime dosing, the availability of clinicians to discuss the side effects, adjustment in dosage, counteractive drug treatment, and continuous assessment.

Noncompliance

Among factors that play a role in treatment noncompliance, such as denial of the illness and lack of supervision, one of the strongest predictors is early onset and persistence of side effects. Noncompliance by itself is a predictor of relapse in patients with chronic mental disorders who are recommended to receive lifelong maintenance treatment. One of the studies in this area found that half of the schizophrenic patients took less medication than recommended, and the reluctance was associated with the side effects of antipsychotic drugs (Van Putten, 1974). On the positive side, many studies indicate improvement in treatment compliance with patient education. Particular approaches in patient education have been proposed that maximize the information conveyed while avoiding suggestibility (Balon, 1999).

Classification of Side Effects

One of the common characteristics of psychoactive drugs is their capability to cross the blood–brain barrier and reach the central nervous system. Consequently, side effects of psychoactive drugs may be generated both centrally and peripherally. Here, the distinction between drug action and drug effect is also relevant: drug action refers to alterations produced by the drug at the molecular level, whereas drug effect (as well as side effect) refers to the observed reactions of the organism. Below, we will examine the behavioral side effects of psychoactive

medications; a review of physiological systems is beyond the scope of this article and can be found elsewhere (Schatzberg and Nemeroff, 1998).

Autonomic

The autonomic nervous system controls homeostasis in the different functional systems in the body mostly through involuntarily mechanisms. Major neurotransmitter systems involve those of acetylcholine and norepinephrine (β or α receptors).

Autonomic side effects of psychoactive drugs are most commonly due to *anticholinergic effects*. Because acetylcholine is widely distributed in the central and peripheral nervous systems, adverse anticholinergic effects can be observed both behaviorally and systemically. Most antiparkinsonian (benztropine, trihexiphenidyl) and the majority of the antidepressant and antipsychotic drugs produce anticholinergic effects. Among the tricyclic antidepressants, tertiary amine tricyclics (amitriptyline, clomipramine, doxepin, imipramine, trimipramine) produce more anticholinergic side effects as compared with secondary amine tricyclics (desipramine, nortriptyline, protriptyline) and tetracyclic antidepressants (amoxapine, maprotiline). As compared with tricyclic antidepressants, anticholinergic side effects with selective serotonin reuptake inhibitors (SSRIs) are minimal. Conventional low-potency antipsychotics (drugs in this category, such as chlorpromazine, thioridazine, and mezoridazine require higher doses to produce equal efficacy than the high-potency antipsychotics) have significant anticholinergic properties as compared with high-potency antipsychotics (fluphenazine, haloperidol, perphenazine, pimozide, tiotixene or (thiothixene), trifluoperazine). Among the new generation antipsychotics, clozapine has the most potent anticholinergic effects, as well as having properties of acetylcholine release. Olanzapine also possesses anticholinergic effects, but less than clozapine. Risperidone, quetiapine, and ziprasidone have minimal anticholinergic activity. Peripheral anticholinergic effects include warm skin, flushing, dryness, dilated pupils (and blurred vision), increased intraocular pressure, dry mouth (if unrecognized this can cause dental problems, such as caries), tachycardia (increased heart rate), reduced acid secretion in the stomach, reduced pulmonary secretions, diminished bowel motility (constipation), urinary retention, and delayed or retrograde ejaculation.

Central anticholinergic effects of psychoactive drugs involve features such as memory impairment, confusion, disorientation, delirium, visual hallucinations, and worsening of preexisting psychotic symptoms. Combination of psychoactive drugs with anticholinergic effects, such as a tricyclic antidepressant, and a low-potency antipsychotic will highly increase the likelihood of an adverse reaction. Geriatric patients are particularly sensitive to anticholinergic side effects and deserve special consideration in the choice of psychoactive drugs and evaluation of a deteriorating course of their clinical situation (*see* Antidepressant Drugs).

Dependence

Dependence is an important component of the side-effect spectrum of some of the psychoactive drugs (barbiturates, benzodiazepines). The *Diagnostic and Statistical Manual of Mental Disorders, fourth edition* (soon to transition to the fifth edition) defines substance dependence as a maladaptive pattern of substance use, leading to clinically significant impairment or distress, as manifested by three or more of the following criteria: tolerance, withdrawal, consumption of large amounts or over a longer than intended time period, persistent desire to cut down, significant effort to obtain the substance, social, occupational sacrifice, and continued usage despite known hazards. It is of note that in this definition a biopsychosocial approach is undertaken. The treatment models for dependency are conducted in a multidisciplinary fashion that address physical, psychological, and environmental factors. Chronic drug use involves tolerance, physical dependence, and psychological dependence. Even though related, tolerance and physical dependence are different concepts:

Tolerance refers to the need of increased amount of a drug with repeated usage in order to achieve the same magnitude of effect. Interestingly, not all of the behavioral effects of drugs show similar tolerance patterns; in the case of benzodiazepines, for instance, tolerance develops for the sedative effects, but not for the antianxiety effects. Tolerance is a reversible condition; abstinence from the drug over a period of time will reduce the amount of drug needed to exert the particular effects. Cross-tolerance is a phenomenon where the tolerance for a particular drug effect operates for another drug effect as well. It is demonstrated by the diminished anticonvulsant effects of the barbiturates in people with chronic alcohol use. Both changes in cellular physiology and behavioral conditioning systems have been postulated as underlying mechanisms for the development of tolerance.

Physical dependence refers to the condition where withdrawal symptoms emerge upon discontinuation of the drug. Withdrawal symptoms are specific to different drugs and quite unpleasant, so that continued use is sought to avoid them. Most withdrawal symptoms are separate from the ones in the intoxication state and can be identified without difficulty.

Endocrine, Metabolic and Cardiovascular

Most antipsychotics elevate serum prolactin secondary to the blockade of dopamine. Increased prolactin may cause menstrual irregularities in females, gynecomastia (abnormal enlargement of the breast) in males, and galactorrhea (spontaneous milk flow) in both females and males. Amenorrhea (complete cessation of menses) occurs frequently in women taking antipsychotics. These changes persist with treatment and resolve with discontinuation. Galactorrhea and amenorrhea may also be observed with tricyclic antidepressants.

Hypothyroidism (decreased function of the thyroid gland) may be associated with long-term lithium therapy. The elderly and females are at greater risk for lithium-induced hypothyroidism. Weight gain is a common side effect of antipsychotics, particularly of new generations, cyclic antidepressants, MAOIs, and SSRIs. Studies suggest that increased weight gain confers a greater risk of insulin resistance, dyslipidemia, and hyperglycemia (Newcomer, 2005). Among the atypical antipsychotic agents, those associated with the greatest risk of weight gain are clozapine and olanzapine. Risperidone, quetiapine, amisulpride, and zotepine are associated with intermediate risk of

clinically significant weight gain. Ziprasidone and aripiprazole have the lowest risk of weight gain, and no known increased risk of diabetes or dyslipidemia. Among typical antipsychotic medications, phenothiazine derivatives (i.e., chlorpromazine, fluphenazine, perphenazine) are associated with dyslipidemia, whereas butyrophenone derivatives (i.e., haloperidol) are not (Newcomer, 2005). Weight changes are also seen with antidepressant medications. The antidepressants most likely to cause weight gain in both the acute and maintenance phases of treatment are amitriptyline and mirtazapine. Nortriptyline is associated with weight gain during the acute phase, but not maintenance treatment. Paroxetine is associated with weight loss in the acute phase, but overall weight gain is observed after long term use. Several other antidepressants are associated with weight loss in the acute phase, but only bupropion has demonstrated long term weight loss (Serretti and Mandelli, 2010). Stimulants (amphetamine, dextroamphetamine, methylphenidate), are associated with appetite suppression and weight reduction. Stimulants are also associated with adverse growth effects (height and weight suppression); however, these effects are minimal (i.e., 2.0–2.7 cm less growth in school age children after 3 years of medication) and can be compensated with drug holidays (Swanson et al., 2007). Cardiovascular disease results in sequelae such as heart attack, angina, and heart failure. Cardiovascular disease risk factors include hypertension, hyperlipidemia, diabetes, and obesity. The risk of having cardiovascular disease has been found to be elevated among those with schizophrenia as as compared with healthy controls (9.4 vs 7.0% in men and 6.3 vs 4.2% in women) (Goff et al., 2005). Metabolic side effects of medications, as well as lifestyle factors such as smoking, lack of exercise, and poor diet lead to a two to three times increased risk of cardiovascular disease mortality among those with schizophrenia than the general population (Newcomer, 2005). Even prior to initiating antipsychotic medications, people with schizophrenia demonstrate increased visceral adiposity and abnormal glucose regulation (Newcomer, 2005). This indicates that medication side effects may not be the sole contributor to increased metabolic risk in this population.

Cardiovascular disease is the most common cause of mortality among patients with schizophrenia, and patients with affective disorders also have higher rates of cardiovascular and cerebrovascular mortality (Newcomer, 2005). In addition to the burden of cardiovascular morbidity and mortality, metabolic side effects attributed to atypical antipsychotics also lead to increased health care costs and disability (Colombo et al., 2008; Chwastiak et al., 2009). Early intervention to modify risk factors and treat hypertension, diabetes, and dyslipidemia in this population is crucial. Current practice guidelines recommend baseline measurements of blood pressure, weight, BMI, waist circumference, lipoprotein profile, and glucose level upon initiation of an antipsychotic agent. Weight should be monitored at 4, 8, and 12 weeks following initiation or change in antipsychotic medication, and every 3 months thereafter. Glucose level, lipoprotein profile, and blood pressure should be followed up 3 months after antipsychotic initiation, and annually thereafter. If the lipoprotein profile is within normal limits, it can be monitored every 5 years (Consensus Development Conference Report, 2004). These parameters should be monitored more frequently for those at higher cardiovascular risk (Casey et al., 2004). Several studies have suggested that treatment with metformin is helpful in reducing weight gain and insulin resistance associated with atypical antipsychotic use. However, further long term studies are needed before implementing this strategy in clinical practice (Björkhem-Bergman et al., 2011; Wang et al., 2012).

Insomnia

Insomnia is the most common transient side effect of stimulants and MAOIs. It is also important to consider that underlying conditions may be linked with insomnia. In most cases, individuals develop tolerance to this side effect after the initial couple of weeks of treatment.

Cardiac

Antipsychotic medication use may increase an individual's risk of developing prolongation of the QT interval, and as a result, can in rare cases lead to ventricular tachyarrythmia and sudden cardiac death. Incidence rates of sudden cardiac death, while rare, are approximately twice as high among current users of both typical and atypical antipsychotic medications as among nonusers (18 events per 10 000 person-years, or less than 0.2%) (Ray et al., 2009). Risk increases with increased antipsychotic dose, older age, and male gender. Incidence-rate ratios increase from approximately 1.45 to 2.64 between those taking low doses of antipsychotic medication as compared with high doses (Ray et al., 2009). Individuals taking high doses of thioridazine have the greatest increased risk (incidence-rate ratio 5.05). Among those taking antipsychotics, the rate of sudden cardiac death in those 70–74 years of age is 10-fold higher than in those 30–34 years of age (4.7 vs 47.6 deaths per 10 000 person-years). Incidence rates are twice as high for men as for women (27.1 vs 12.9 deaths per 10 000 person-years).

Neurological/Behavioral

Cognitive Effects

Even though the motor and cognitive functions of the brain do not operate independently from each other, specific neuropsychological tests that capture primarily motor or cognitive functions have been applied to measure the effects of psychoactive drugs in these domains. While several studies comparing neurocognitive improvement with antipsychotic treatment suggested advantages with atypical agents over typical agents (Keefe et al., 2004; Velligan et al., 2003) more recent evidence indicates no difference (Keefe et al., 2007). When perphenazine was compared with equivalent doses of atypical antipsychotics (olanzapine, risperidone, and quetiapine), all groups demonstrated a small improvement in processing speed, reasoning, working memory, verbal memory, and attention. Most of the improvement occurred by 2 months of treatment. Prior evidence suggesting neurocognitive worsening with typical antipsychotics may have been due to use of higher doses of high potency medications (i.e., haloperidol), resulting in extrapyramidal side effects and need for co-administration of anticholinergic medications. Double-blind studies comparing the new generation antipsychotic clozapine and the conventional antipsychotic haloperidol revealed a significant

interaction on measures of executive/attention, verbal fluency, and visuospatial functions (Lee, 1999). Further analysis revealed that some of these effects resulted from worsening performance of the haloperidol-treated patients. Patients treated with clozapine showed an insignificant improvement (Buchanan et al., 1994). Anticholinergic doses have been associated with poor verbal learning, verbal fluency, and motor speed. The cognitive effects of antipsychotic medications are especially salient since schizophrenia is associated with cognitive deterioration over time. Differences in academic achievement between those who later develop schizophrenia as compared with their healthy peers are evident as early as the first grade, and the gap continues to widen by twelfth grade. There is also a substantial decline in cognitive ability associated with the initial psychotic episode (Bilder et al., 2006). Lithium may also interfere with memory and motor speed functions. Valproate, carbamazepine, and topiramate may reduce the speed of cognitive processing (Loring et al., 2011; Hessen et al., 2006). Benzodiazepines may cause slowed cognitive function, impaired memory, and behavioral disinhibition.

Motor Effects

Conventional antipsychotic drugs (haloperidol, fluphenazine), and to a lesser extent, new generation antipsychotic drugs (risperidone, olanzapine), some of the selective serotonin reuptake inhibitors (sertraline, fluoxetine), and cyclic antidepressants (amoxapine) affect motor functions of the EPS. Acute conventional antipsychotic treatment interferes with simple repetitive motor tasks such as finger tapping. These effects are related to the drugs' dopamine blocking properties in the basal ganglia. Lithium and valproic acid may cause hand tremors. Stimulant use may be associated with development or worsening of tics.

Acute motor effects of the conventional antipsychotics include parkinsonism, dystonic reactions, and akathisia. The major chronic effect of antipsychotic use is tardive dyskinesia. *Parkinsonism* is a word derived from Parkinson's Disease, which is characterized by tremor, rigidity, and bradykinesia (slowed movement). All three features are observed in susceptible patients in the initial phases of treatment. Tremor with a regular rate may be observed in the hands and feet, and is present at rest. Tremor around the mouth also occurs. Akinesia (absence of movement) of the facial muscles sometimes leads to lack of expression which is known as masked face. Patients walk slowly, sometimes with shuffling, short steps, and the normal arm swing is diminished. Rigidity of muscles can be felt on examination; cogwheeling (increased tone in all directions of movement and superimposed ratchet-like resistance) may be elicited. Handwriting is characteristically small and tremulous.

One of the most disturbing side effects of antipsychotic medications (mostly of the high-potency conventional ones and some of the new generation antipsychotics) is akathisia, a subjective experience of motor restlessness. Patients complain of not being able to sit still, they pace in hallways, constantly move their legs to help the discomfort. They describe it as "… I want to run a hundred miles … ." Significant akathisia may lead to insomnia because of having trouble lying in bed. It may be accompanied by a feeling of anxiety and agitation. Restlessness and agitation are frequently observed as part of psychosis in the absence of any drug treatment. Drug-induced akathisia therefore is very important to diagnose differentially for appropriate treatment. If it is mistaken as psychosis-related agitation, increased antipsychotic drug dose will only make it worse. Akathisia has been identified as a predictor of antipsychotic noncompliance. Several treatment options are available.

Acute dystonic reaction is another side effect of the conventional antipsychotics that requires immediate treatment. Dystonic reactions consist of abruptly developing muscle contractions which frequently involve the muscles of the face, tongue (protrusions, twisting), neck (spasmodic torticollis), jaw (trismus), eyes (oculogyric crisis, blepharospasm), and limbs. It is most common in young men in the initial phases of treatment. It is treatable with anticholinergic and antihistamine drugs. Prophylactic treatment with these drugs may increase the chances of compliance.

Tardive dyskinesia is a long-term side effect of conventional antipsychotics characterized by involuntary choreiform (random, brisk) or athetoid (slow, regular continuing twisting) movements of the head, face, tongue, limbs, and the trunk. These movements may range from mild and unrecognized to severe and incapacitating. Movements around the mouth are the most common. Dyskinesia may be exacerbated with stress and disappears with sleep. About 10–20% of patients treated with conventional antipsychotics for more than a year develop tardive dyskinesia. Children, women, the elderly, patients with brain damage or mood disorders constitute high-risk groups. While tardive dyskinesia is associated with antipsychotic use, 1–5% of patients with schizophrenia who lived before the antipsychotic era have been reported to exhibit similar dyskinetic movements. Thus, tardive dyskinesia may be related to the pathophysiology of schizophrenia. The new generation antipsychotics (clozapine, olanzapine, risperidone, quetiapine, ziprasidone) were previously believed to have significantly lower incidence of EPS side effects and tardive dyskinesia as as compared with the conventional antipsychotics (Correll et al., 2004). However, more recent studies find minimal difference between first and second generation antipsychotics in the incidence of EPS side effects or tardive dyskinesia over a period of 18 months at equivalent doses (Woods et al., 2010; Miller et al., 2008). It is suggested that earlier discrepancy was based on use of higher doses of first generation agents. Numerous animal studies have demonstrated that clozapine fails to induce EPS-related movements, and it is the only antipsychotic that might have a potential to prevent tardive dyskinesia from deteriorating (*see* Schizophrenia, Treatment of).

Sedation

Sedation is a common side effect of most antipsychotics, mood stabilizers, benzodiazepines, barbiturates, and antidepressants (tertiary amine cyclic antidepressants, MAOIs, trazodone, sometimes with other SSRIs, venlafaxine, and nefazodone). In particular clinical situations, such as severe agitation, sedation may be desirable, whereas in others such as a negative symptoms of schizophrenia (affective flattening, lack of spontaneous speech, avolition), or depression with hypersomnia, it would not be. The choice of drug therefore largely depends on the clinical necessity. In undesirable conditions (night time dosing, reduction in dose) switching to a less sedating medication is considered.

Seizure

Antipsychotic drugs, particularly the ones with low potency reduce the seizure threshold. In a patient with no history of seizure disorder, incidence is low and no prophylactic treatment is warranted. Patients with a history of seizure disorder deserve special consideration. Clozapine increases risk of seizures in a dose-related fashion. The frequency of seizures in those taking clozapine is 1.3% overall, with greater risk observed during the initial titration phase than during the maintenance phase (Pacia and Devinsky, 1994). Individuals receiving doses equal to or greater than 600 mg daily have a 1.9% risk of seizure at 6 months (Pacia and Devinsky, 1994). Anticonvulsants such as valproic acid can benefit the patient to continue treatment with clozapine.

Among the antidepressants, clomipramine and amoxapine may lower the seizure threshold while incidence of seizures with SSRIs and Serotonin and Norepinephrine Reuptake Inhibitors (SNRIs) is low, but present. Estimated seizure risk for these agents are 0.4–1.0% for tricyclic antidepressants, 0.26% for venlafaxine, 0.2% for fluoxetine, 0.15% for bupropion, 0.1% for paroxetine, and less than 0.1% for sertraline (Dunner et al., 1998). Tricyclic antidepressants, MAOIs, anticonvulsants, lithium, and antipsychotics may also induce myoclonic (irregular rapid muscle contraction) movements.

Hypomania/Mania

Even though it remains controversial, one of the important side effects of antidepressant treatment is the induction of hypomania/mania. In a patient with no history of mania, undergoing antidepressant treatment, emergence of manic features merits consideration of the possibility of drug-induced mania. In patients with bipolar disorder, on the other hand, the risk of mania induction with sole antidepressant (in the absence of a mood stabilizer) treatment is established (Truman et al., 2007).

Delirium

Delirium associated with psychotropic medication is most likely to occur in the elderly population and those with dementia. The psychotropic medication classes most likely to cause delirium are anticholinergics (such as benztropine and trihexylphenidyl), benzodiazepines, levodopa, and tricyclic antidepressants. Infrequently, worsening of psychosis, confusion, and agitation may occur with antipsychotic treatment. Most cases are, however, associated with those antipsychotics with greater anticholinergic properties such as clozapine and chlorpromazine, with polypharmacy, or in the elderly (Moore and O'Keefe, 1999). While several psychiatric medications have anticholinergic properties, many other commonly prescribed medications do as well, such as antiemetic, anticoagulant, cardiac, genitourinary, allergy, and muscle relaxant medications (Cancelli et al., 2009). The additive anticholinergic properties of multiple medications are more likely to induce delirium.

Neuroleptic Malignant Syndrome

This is a potentially life-threatening complication of the antipsychotic treatment characterized by muscle rigidity, hyperthermia, mental state changes (stupor, agitation, confusion), and autonomic dysfunction (blood pressure instability, increased pulse, respiration, sweating). The incidence is about 0.1% of patients exposed to conventional antipsychotics, and more likely to occur in men (approximately 70% of cases) (Troller et al., 2012). High-potency antipsychotics may have a higher risk than low-potency antipsychotics. Rhabdomyolysis (muscle necrosis) may occur that leads to myoglobinuria (passing a muscle-related protein – myoglobin – in urine) and subsequent renal failure. Immediate intervention is necessary. As opposed to conventional antipsychotics, NMS with atypical antipsychotics have been shown to manifest in different ways. Patients tend to be younger (age 47 vs 62), are less likely to present with muscle rigidity (especially in the case of clozapine), and the mortality rate is lower (3 vs 16.3% with conventional agents) (Troller et al., 2012).

Placebo Effects

A placebo is a pharmacologically inactive agent administered in a group of patients in a double-blind clinical trial to improve the true estimate of the active agent's efficacy and side effects. Placebo effects may be relevant to the concept of side effects from the perspective of experiences of drug effects in the absence of drug action. Substantial evidence suggests emergence of physiological changes associated with placebo administration. While placebo drug efficacy approaches significant percentage of patients in some clinical trials, incidences of side effects are also variably present. Placebo response rates vary widely among medication trials for depression, anxiety, and schizophrenia (21–70%) depending on the outcomes measured (Laporte and Figueras, 1994).

Sexual

In males impotence, decreased libido, changes in quality of orgasm, priapism (painful erection), and erectile and ejaculatory disturbances have been reported with antipsychotic use. In women orgasmic dysfunction and decreased libido are frequently observed with antipsychotic treatment. Sexual dysfunction associated with SSRI use impairs quality of life, and is a reason for noncompliance. Bupropion and nefazodone may have a more favorable profile as compared with TCAs, MAOIs, and venlafaxine. In contrast, some antidepressants are prescribed for the treatment of premature ejaculation.

Children and Adolescents

Children and adolescents experience higher rates of certain antipsychotic-induced side effects such as sedation, extrapyramidal side effects (except for akathesia), withdrawal dyskinesia, prolactin elevation, and weight gain. Young people are less likely to develop tardive dyskinesia or diabetes than adults treated with antipsychotics (Correll et al., 2011). Children may have more prominent weight gain during treatment with antipsychotic medications than adults (Newcomer, 2005). The risks of obesity, as well as cardiovascular, cerebrovascular or hypertensive adverse events are increased with the concomitant use of other psychotropic agents (Maayan and Correll, 2011).

Psychostimulants are often prescribed for the treatment of ADHD in children. These agents have the potential to cause

delayed onset of sleep, appetite suppression, headache, abdominal pain, growth delay, tics, and increases in pulse and blood pressure (Correll et al., 2011).

SSRI and SNRI medications have been found to be effective in the treatment of depression, anxiety, and obsessive-compulsive disorders in children and adolescents. Young people most frequently experience transient side effects such as nausea or headache. Rarely, they may also experience behavioral activation. Earlier studies led to concern for increased suicidal thinking or behavior among antidepressant-treated youth (Brent et al., 2009; Hammad et al., 2006). Subsequent studies indicate that depressed youth receiving antidepressants are at lower risk for completed suicide than those who are untreated, especially when cognitive behavioral therapy is added to medication management (Correll et al., 2011).

Elderly

Older individuals are more sensitive to side effects of psychotropic medications. Most notably, the elderly may experience more dyskinesia, anticholinergic side effects, cardiovascular effects, and sedation. Studies have indicated that elderly patients with schizophrenia may benefit from atypical antipsychotic agents over typical agents due to lower rates of dyskinesia and improved quality of life (Ritchie et al., 2003). Elderly patients may not exhibit significant weight gain with atypical antipsychotic use, but nonetheless are at increased risk of adverse health outcomes due to insulin resistance, dyslipidemia, and glucose intolerance with these agents (Newcomer, 2005).

Quality of Life and Side Effects

The World Health Organization has defined Quality of Life as:

> An individual's perception of their position in life in the context of the culture and value systems in which they live and in relation to their goals, expectations, standards and concerns. It is a broad ranging concept incorporating in a complex way the person's physical health, psychological state, level of independence, social relationships, personal beliefs and their relationship to salient features of the environment.
>
> WHOQOL, 1999

This definition emphasizes a comprehensive approach in the assessment of quality of life. Disciplines of medicine, particularly cancer research have concentrated on global measures of quality of life, as symptom improvement by itself does not account for it. In psychiatry, the slow pace of research in this area may be due to difficulties of valid and reliable quality of life assessments from psychiatric patients. Pioneered by Lehman (Lehman et al., 1982), renewed interest has led to research in debilitating psychiatric disorders such as schizophrenia and demonstrated the significance of a multidisciplinary treatment model. While the strongest predictor of symptom improvement is identified as compliance with recommended drugs, its sole impact on quality of life in the long term is yet to be elucidated. The issue gets complicated due to the side-effect profile of psychoactive drugs, which may mimic the symptoms of diseases, and also due to the direct impact of side effects on quality of life. For patients with schizophrenia, symptoms, their severity, and subjective distress caused by side effects accounted for half the variance in quality of life (Awad et al., 1997).

In one study where 53 schizophrenic outpatients treated with depot neuroleptics were studied, 70% complained about side effects when 94% were found to experience them. Among the patients who denied having side effects, 87% had some form of it (Larsen and Gerlach, 1996).

The recognition of the negative impact of tardive dyskinesia on, for instance, patients' self-esteem, incapacity, and perception by society has been essential toward targeting more favorable treatments. The introduction of new generation psychoactive drugs, particularly antidepressants and antipsychotics is therefore encouraging. Such drugs have not only led to superior efficacy, but also have more favorable side-effect profiles. However, there remains significant room for further improvement in side-effect profiles of psychoactive drugs.

Abstract

Psychophysics is a scientific approach to the measurement of mental processes. In *Elemente der Psychophysik* in 1860, Gustav Fechner defined the field, quantified Weber's law, created a theory of judgment errors in sensory comparisons, and proposed a logarithmic law of sensation strength. In 1927, theoretical advances by Thurstone expanded the applications of psychophysical methods to stimuli not measurable on a physical scale, thereby permitting measurements of attitudes, preferences, and feelings. Stevens (1956) argued against these ideas and proposed, instead, a power law of sensation strength, an idea previously proposed by Plateau (1872). New experimental data required both camps to accommodate the influence on performance of 'cognitive factors,' which caused deviations from the power law of sensation. In classical psychophysical experiments, the effects of cognitive factors led to the theory of ideals, the theory of signal detection, receiver operating characteristics, and a sequential theory of psychological discrimination. At the beginning of the twenty-first century psychophysics is poised for major theoretical advances toward more refined and more extensive measurements of mental processes.

Introduction

Psychophysics is a scientific approach to the measurement of mental processes. The empirical laws of psychophysics are based on measures such as the magnitudes of stimuli just noticeably different from each other, the proportion of errors made when comparing two stimuli, the time required to complete such judgments, and self-reports of the confidence in comparative judgments or the strength of a stimulus. Some laws define relations between physical events and their mental representations such as sensations and feelings. The theories of psychophysics provide explanations of these empirical relations and suggest neural mechanisms that give rise to experimental results.

Nineteenth-Century Psychophysics

The first law defined the 'just noticeable difference' (jnd) in sensation. A jnd occurred, phenomenally, when an increment in the size of a physical stimulus evoked a sensation of a difference in magnitude. The German physiologist Ernst Heinrich Weber (1834/1978) discovered, for many sense modalities, the increment in a physical stimulus needed to evoke a jnd. Leipzig physicist Gustav Fechner (1860/1966) quantified Weber's observations and created the First Law of Psychophysics, Weber's law,

$$\Delta s/S = c \qquad [1]$$

where S is the magnitude of the physical stimulus, Δs is the just noticeable increment, and c is called Weber's constant. For discriminating lifted weights $c = .043$. Thus, an initial weight of 1000 g will require an increment of 43 g (to $S + \Delta s = 1043$ g) before the new weight will feel just noticeably different from 1000 g.

The subjective nature of these self-reports led Fechner to wonder whether the person experiencing a jnd could identify which of the two stimuli, S or $S + \Delta s$, was larger. Fechner discovered that two stimuli may feel just noticeably different, but may be identified correctly in only about 75% of the comparisons made. Fechner described these experiments and officially established the field of psychophysics in the two-volume *Elemente der Psychophysik* (1860/1966).

In *Elemente* Vol. 1, Fechner created a theory of how humans comparing two sensory stimuli, such as a pair of lights for brightness, two weights for heaviness, or two lines for length, make errors in their judgments. The theory assumed that the sensory system provided the mind with measurements of the external world. However, the process by which the sensory/nervous system created an internal sensory representation of an external physical stimulus introduced error into the measurement. A fixed weight might at one time feel heavier, or lighter, depending upon the amount of error added to, or subtracted from, the true sensory value for the external stimulus. Extending the theory of error created by Gauss (1809) for physical measurement devices, Fechner invented a theory of judgment about invisible mental events that allowed him to measure the size of the error in the nervous system.

Figure 1 illustrates the essential features of Fechner's theory as it applies to the comparison of two just noticeably different weights, W_a and W_b. Along the abscissa are true sensory values, μ_a and μ_b, for the two weights undergoing comparison by lifting each once. Two Gaussian (normal) probability distributions describe the error of sensory measurement and surround the true sensory values of μ_a and μ_b. Fechner postulated that a (decision) threshold, t, for deciding which weight was the larger existed exactly midway between μ_a and μ_b, that is, at

$$t = \mu_a + (\mu_a - \mu_b)/2 \qquad [2]$$

A lifted weight sensed to be greater than this threshold was thought to be the heavier weight.

The shaded area of Figure 1 to the right of t represents the probability of making an error of judgment in deciding that the smaller of two stimuli was in fact the larger. The symmetric nature of Fechner's theory predicts that the probability of judging the larger of two stimuli to be the smaller equals the same probability, and is shown by the shaded area to the left of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.43084-9

Figure 1 Fechner's theory of mental judgment proposed that Gaussian variability perturbed nervous system transmission of peripheral sensory stimuli. Weight W_a was incorrectly judged to be heavier than weight W_b whenever the sensory value for W_a exceeded the value t. Similarly, W_b was incorrectly judged to be lighter than W_a whenever the sensory value for W_a was less than t. The probabilities of an error are represented by the shaded areas to the right and left of t.

the threshold, t. The two error probabilities increase as the variability in the sensory system increases. Such an increase in variability causes a greater spread in each Gaussian probability distribution.

Fechner's goal was to measure the invisible variability of the sensory system in units of the physical stimuli. As a measure of variability, Fechner chose the value $\sqrt{2}\sigma$, Gauss's measure of the spread of the Gaussian distribution. The value of σ, a parameter of the Gaussian probability distribution, creates a scale of measurement units along the abscissa of Figure 1. The unknown value for t is located at unknown number of σ units above the true sensory value μ_a. However, once the probability of an error of judgment is known, one can determine from tables (many created by Fechner) the corresponding distance in σ units of the (decision) threshold t above the true sensory value μ_a. For example, if the probability of an error in judging which weight is larger equals .25, then the (decision) threshold, t, is $.674\sigma$ units greater than the true sensory value μ_a.

To determine the value of σ, Fechner replaced the unknown values of μ_a and μ_b by the physical values that gave rise to them, W_a and W_b. The distance from μ_a to t is defined as $t = .675\sigma$. That is,

$$t = .675\sigma = (W_b - W_a)/2, \text{or} \quad \sigma = (W_b - W_a)/(2^*.675) = (W_b - W_a)/1.35 \qquad [3]$$

Using the example above, the smaller of the two just noticeably different weights equaled 1000 g, and the larger, 1043 g (and the probability of an error equaled .25). Thus the measure of variability is

$$\sigma = (1043\,\text{g} - 1000\,\text{g})/1.35 \approx 32\,\text{g} \qquad [4]$$

Fechner summarized these ideas in a famous formula that is the Second Law of Psychophysics:

$$t = hD/2 \qquad [5]$$

Here $h = 1/\sqrt{2\sigma}$, and D equals the difference between two physical stimuli, $W_b - W_a$. The term h measures the sensitivity of the system. When σ is large, indicating great sensory variability and a small value of h, many errors occur and the system is said to be insensitive. A small value for σ leads to few errors, a larger value for h, and the system is said to be more sensitive.

This first method of measuring the invisible, internal variability of the sensory system established psychophysics as a truly scientific discipline. Measuring the unknown variability of the sensory/nervous system in units of physical stimuli marks a revolution in the scientific investigation of the human mind. This powerful theory became the basis for the fields of experimental psychology and statistical hypothesis testing.

Fechner also theorized, in *Elemente* Vol. 2, about a measure of how much sensation a stimulus generated. Placing each jnd in a sequence is a way of adding together phenomenally equal

units of sensation. Using Weber's law as a base, Fechner argued that on a continuous scale of sensation Weber's constant,

$$c = \Delta s/S \quad [6]$$

is a differential equation. Integrating the differential equation is equivalent to adding together the jnds of sensation increments to obtain a total amount of sensation. The result of the integration is called Fechner's Law of Sensation: the total amount of sensation generated by a stimulus is given by the equation

$$\xi = k\log_e(S) \quad [7]$$

where k is a constant of integration, S is the magnitude of the stimulus, and ξ is the amount of sensation.

Fechner's law is perhaps the most widely known of any psychophysical law. Yet criticisms of Fechner's idea never abated (Luce and Edwards, 1958; Stevens, 1975; Krueger, 1989; Lockhead, 1992; Murray, 1993). The notion of adding together jnds to create a yardstick of sensory measurement is appealing, but the 'law' provides for no independent experimental means for testing its prediction. How is internal sensation to be measured, or as Laming (1997) wonders, 'Can sensation be measured?' The answers to this question fall in the domain of representational measurement – how numbers are attached to qualitative objects (Narens, 2007).

The father of American philosophical pragmatism, C. S. Peirce, put Fechner's ideas to another test. Peirce argued that the sense of confidence in a judgment was a sensation directly related to the probability of making a correct judgment. Peirce's law states that if C is the average confidence in a judgment, p the probability of making a correct judgment, and k a constant, then

$$C = k\log_e[p/(1-p)] \quad [8]$$

Like Fechner's law there is a logarithmic relation between two variables. However, in this case each variable can be measured through direct experimentation. Peirce and Jastrow (1884, see Link, 1992; Vickers, 1979), and later experiments, confirmed this prediction (Link, 2003).

The profound impact of Fechner's Psychophysics led to Wilhelm Wundt's 1879 creation of the first psychological laboratory at Leipzig University. A student, James McKeen Cattell, proposed a new measure of the amount of sensation generated by perfectly discriminable stimuli, as opposed to jnd stimuli. Reaction time, the time taken to respond to the presence of a stimulus, could measure stimulus strength. Cattell's experiments showed remarkable decreases in response time as stimulus magnitude increased. Later (Piéron 1914, see Welford, 1980; Luce, 1986) proposed the general principle Piéron's law:

$$\mathrm{RT} = a + kS^{-\beta} \quad [9]$$

where a is a constant due to nonsensory effects, k and β are constants, and S is physical stimulus intensity.

Twentieth-Century Psychophysics

By 1900, Fechner's experimental methods and a measure of the response threshold, t, in units of the physical stimulus were well established as part of the new psychology's experimental methods. To create a uniform basis for comparison of experimental results, the stimulus generating a value of t corresponding to 75% correct responses was chosen as a standard measure of sensitivity. When a large stimulus was required for 75% correct responses the responder was less sensitive than when a smaller stimulus generated 75% correct responses. Thus, thresholds became a tool useful in comparing performances across subjects and stimuli. The choice of this threshold value derives in part from the often-used nineteenth-century measure of variability the 'probably error.' Uses of the 75% threshold are still found in the current literature.

Determining the stimulus that generated 75% correct response was formalized by Urban (1907). His method of constant stimuli required that a fixed set of comparison stimuli be compared at random against a fixed standard stimulus. For example, a set of weights varying from 88 to 112 g, compared at random against a fixed standard of 100 g, generated a series of 'heavier' responses varying from near zero for the 88 g comparison to nearly 100% for the 110 g comparison. Urban defined this function as a 'psychometric function.' An estimate of the comparison weight generating 75% correct heavier was then estimated by fitting a smooth curve to the empirical psychometric function. In vision studies the psychometric function is called the 'frequency of seeing curve.'

Urban suggested that another response is available beyond the usual two choices when using the method of constant stimuli. This new response alternative allowed for the judgment of equal when no difference between the standard and comparison was perceived. Studies of equality judgments themselves became stable features of psychophysical experiments for many decades and led to questions about sameness versus difference.

Measuring the magnitudes of perfectly discriminable stimuli remained elusive. Thurstone (1927, 1955), Bock and Jones (1968) proposed that every stimulus projects a value on an internal psychological continuum. For example, stimuli such as crimes may vary on a continuum of the seriousness of crime. When asked to judge which of two crimes is more serious, a subject will compare the two crime's seriousness values and choose the crime with the greater seriousness value. This is the famous Law of Comparative Judgment. For each subject, crimes vary in their degree of seriousness but for a fixed subject each crime's seriousness is fixed. For a fixed crime, individual differences across subjects created variability across the dimension of seriousness of crime. Thurstone represented this variability by a Gaussian distribution of seriousness values. For a group of subjects the theory is formally identical to Fechner's, but the emphasis on measuring stimulus values, rather than variability, created a powerful new direction in psychophysical research.

Thurstone proved that by comparing all stimuli against each other, each stimulus could be measured on the underlying psychological continuum. Now, mental phenomena as elusive as attitudes could be measured. In an application to classical psychophysics, Guilford (1928, see 1954) used the method to determine heaviness values for difficult-to-discriminate lifted weights.

World War II placed new demands on psychologists. As an example, SONAR (SOund Navigation And Ranging) allowed for the detection of enemy submarines shadowing convoys or

warships in wait for an opportunity to attack. A SONAR operator wearing earphones listened to amplified underwater sounds in an effort to detect the presence of an enemy submarine. In the colorful language of signal detection, the operator made a hit when detecting a submarine and a false alarm when claiming a submarine was present when it was not. The human operator suffered stress due to fatigue and required a period of learning before providing a sufficiently low rate of false alarms to be of military effectiveness.

The obvious theoretical treatment of this problem of recognizing the sound of a submarine imbedded in the noisy sounds of the underwater environment is the traditional theory of discrimination due to Fechner. The sound of the noisy underwater environment is one stimulus and a second stimulus is created by embedding the sound of a nearby submarine into the noise. The SONAR operator must be continually alert so as not to miss the presence of an enemy. As was soon discovered, both fatigue and prior information affected the ability to detect a signal embedded in noise.

Experiments from many different laboratories presented conflicting pictures of human signal detection. To account for many experimental results, Peterson et al. (1954) developed the Theory of Signal Detectability. The theory is an extension and deeper development of the theory for deciding between two stimuli first described by Fechner (1860). In Figure 1 let the upper probability distribution represent the distribution of psychological values generated by just the noise alone as heard by the SONAR operator. The lower probability distribution represents the distribution of psychological values when the submarine (the signal) is also present. Let t, called a criterion in signal detectability theory (SDT), be the smallest value needed to respond that a submarine is present. The shaded area to the right of t in the upper distribution represents the probability of a false alarm, the probability of claiming a submarine to be present when only noise is actually present. The unshaded area to the right of t in the lower probability distribution represents the probability of a hit, of detecting a submarine when present.

To measure performance, hit and false alarm probabilities may be plotted against each other in a receiver operating characteristic (ROC) space as shown in Figure 2. In Figure 1 the false alarm probability equals 1 minus the hit probability. This probability lies somewhere on the antidiagonal of Figure 2 depending on the difference between the means of the two probability distributions. If $\mu_a = \mu_b$, then the distributions are identical, and the probability of a hit equals .50 as does the probability of a false alarm. This outcome is represented in Figure 2 at the point where the antidiagonal and the main diagonal, showing guessing, intersect. As the mean of the signal plus noise distribution increases, this point will ascend the antidiagonal, showing an increase in the probability of a hit and a decrease in the probability of a false alarm, due to better discriminability of the two stimuli. This is in accord with Fechner's theory of discrimination.

However, factors were soon discovered that drove the hit and false alarm probabilities to deviate from the antidiagonal. The curved line in Figure 2 represents hit and false alarm probabilities that occur if the value of t in Figure 1 is allowed to vary away from its position midway between the means of the

Figure 2 Illustrations of receiver operating characteristics predicted by different psychophysical theories of discrimination for judgments between two stimuli. The abscissa is the probability of an incorrect response to one of the two stimuli (false alarm), and the ordinate is the probability of a correct response (hit) to the other stimulus. The main diagonal represents guessing. Different ROCs correspond to theories described in the text: High threshold theory (HTT), signal detectability theory (SDT), low threshold theory (LTT), and variable sensitivity theory (VST). All these ROCs are given a unitary basis by Link (1992).

two distributions. At the most extreme, with t to the very left side of Figure 1, hits and false alarms occur with probability 1, the areas under the probability distributions to the right of t. This point is at the upper right hand corner of the ROC curve for SDT. As the value of t increases, the hit and false alarm probabilities sweep out the smooth curve labeled SDT in Figure 2. Many experiments supported this view of how changes in performance were caused by changes in the value of t. Changes in the value of t away from its midway position between the two means represented 'response bias.'

Many sensory experiments produced the form of the ROC predicted by SDT (Swets et al., 1961; Swets, 1964, 1996). Experimental subjects were able to bias responding in the light of knowledge about the relative frequencies of the two stimuli, monetary payoffs for correct or error responses, and verbal suggestions. Additional research revealed other forms of the ROC inconsistent with the predictions of SDT. Blackwell (1953) suggested a high threshold theory (HTT), with guessing occurring when the stimulus produced a sensory value less than a threshold. The straight line ROC in Figure 2 illustrates the predicted HTT relation between hits and false alarms replicated in many experiments. Luce (1963) suggested a low threshold theory (LTT) that generated the 'dog-leg' ROC illustrated in Figure 2. Atkinson (1963) also suggested the variable sensitivity theory (VST) that generated the HTT ROC and the uppermost ROC shown at the upper left corner of Figure 2. All these various theories received solid support from experimental results.

A consolidation of these various ROCs resulted from a theory suggesting a different account of their common occurrence. Link (1975, 1992) and Link and Heath (1975) derived these various ROCs from a distribution-free

Figure 3 Ten accumulations of comparative differences across time epochs when two stimuli are actually identical. Each stochastic path represents the result of a single experimental trial. The upper and lower response thresholds determine which of two possible responses can occur. The distance between thresholds can be manipulated by the subject as more or less total comparative difference is required for making judgments. Response bias is determined by the starting position of the accumulation process. Link (1978, 1992) shows how response time deadlines imposed on a subject's performance cause the subject to move the thresholds, thereby reducing response time and response accuracy.

sequential theory of psychological judgment. In this relative judgment theory (RJT) comparative differences accumulate during the process of decision making until either an upper or a lower response threshold is exceeded, then a response occurs. As shown in the examples in Figure 3, even when there is no difference between two stimuli, the accumulation of comparative differences can generate very fast response acquisition for some experimental trials and much slower responses on other trials, although nothing changes in either the stimuli or the subject making decisions.

As these response thresholds are manipulated by subjects to meet the demands of the experimental setting all the different ROCs result. By increasing the distance between thresholds subjects require more total comparative difference before responding, leading to longer response times and greater accuracy of discrimination. For a fixed difference between the upper and lower thresholds moving the starting position of the process from the upper threshold toward the lower threshold will sweep out performances like SDT. The HTT ROC occurs when subjects hold the lower threshold constant but vary the upper threshold in response to performance demands. For LTT first one threshold is held constant and the other threshold is allowed to vary. Then the previously variable threshold is held constant and the other threshold varies. The VST ROC results from using two different sets of response thresholds to meet performance demands (Link and Heath, 1975; Link, 1992). Especially important to RJT are predicted relations between response probabilities and response times, between the psychometric function and the corresponding chronometric function (Link, 1975, 1992). The theory spawned a new era of random walk theories applied to psychological research.

However, perplexing irregularities in the predicted ordering of probabilities in the Thurstonian full paired comparison matrix were the basis for Clyde H. Coombs to propose an important extension of the Law of Comparative Judgment, the Theory of Ideal Comparisons. Rather than comparing two stimuli against each other, Coombs (1964) proposed that each stimulus be compared against an ideal defined on a psychological continuum. Choosing between two stimuli equally distant from the ideal led to indifference with respect to them and the peculiar response proportions often observed in some paired comparison matrices. For example, a continuum of shades of gray may contain an ideal gray. However, two shades of gray equally distant on either sides of this ideal would be equally preferred. The subject faced with choosing between either of these stimuli as to which was the better gray would be indifferent to them and chose either with probability .50.

In spite of its immense value, the Law of Comparative Judgment said nothing about how response time or confidence should vary when stimuli are compared against each other. (Johnson 1939, see Link, 1992) combined choice, confidence, and response times (RT) in an experiment on judgments of differences between line lengths and discovered Johnson's law:

$$\mathrm{RT} = a(10)^{b(1-C)} \qquad [10]$$

where $0 \leq C \leq 1$ is a measure of confidence and a and b are constants. Johnson's law, together with Peirce's law, suggests a relationship between confidence and response probability. Link (2003) confirmed predicted relations between response time and the discriminability measures of the sequential theory of decision making first proposed in 1975.

Stevens (1975) dismissed the theoretical reasoning leading to Fechner's law and the Law of Comparative Judgment, and proposed an alternative formulation for determining the amount of sensation generated by a single stimulus. According to Stevens, "equal stimulus ratios produce equal sensation ratios." This idea is the basis for the famous power law of sensation,

$$\xi = \lambda S^{\gamma} \qquad [11]$$

where ξ is the strength of response to a stimulus of intensity S, λ is a nonsensory scaling constant, and γ measures the effects of peripheral sensory transducers that are unique to a sensory modality (Plateau, 1872; Laming and Laming, 1996). Stevens (1975) determined power law exponents for many sensory quantities and gave convincing evidence of the satisfactory representation of stimulus strength provided by the power law.

Although the power law contradicts Fechner's law, the power law must be consistent with Weber's law. Link (1992) derived the prediction that Stevens' exponents and Weber's constants are reciprocals of each other. Using values reported by Teghtsoonian (1971), the prediction holds for sensory quantities investigated by Stevens such as shock, heaviness, loudness, finger span, vibration, saturation, taste, and brightness. Ekman's law (Ekman, 1956) provides yet another relation between jnds and the power law by asserting that increments in sensation on a psychological continuum are a linear function of sensation magnitude, as if Weber's law applied to both the psychological continuum and the physical stimulus continuum. Gescheider (1997) shows how Ekman's law leads to Stevens' power law.

Cognitive factors also affect the magnitude of response. For example, Parducci (1965) develops a theory of how the range and frequency of stimuli affects judgments. Birnbaum (1974) examines context effects on comparative judgments and Birnbaum and Mellers (1978) examine ratio and difference judgments of distances in mental maps. Baird (1996) suggests that beyond the sensation effects caused by the peripheral nervous system are cognitive factors that demand a reinterpretation of the power law. Proposing a complementarity theory of psychophysics, Baird accounts for a wide variety of experimental results unaccounted for by the power law. In a different approach, Norwich (1993) developed a general theory of the sensory language of the brain. Using the fundamental equation

$$F = kH \qquad [12]$$

where F is a perceptual variable, k is a positive constant, and H is a measure of entropy, Norwich derives both the power law and Fechner's law from the same basis. Poulton (1989) reveals how 'biases may conceal the linear relation between magnitude judgments and the stimulus magnitudes that appear to the observer to be equally spaced.' Warren's (1958) physical correlate theory holds that sensory magnitude estimates are based upon the manner in which sensory excitation is correlated with the quantity of a physical attribute of the stimulus.

For choices between many stimuli, Luce (1959, see Falmagne, 1985) created the choice axiom. Let $S_1, \ldots, S_n$ be a set of commensurate stimuli. Luce's choice axiom states that the probability of choosing stimulus S_i is

$$W(S_i)/\left(\sum_n W(S_n)\right) \qquad [13]$$

where W_i is the psychophysical value of stimulus S_i. For example, given five breakfast cereals, $B_1, \ldots, B_5$, the probability of choosing cereal B_i is

$$p_i = W(B_i)/\left(\sum_h W(B_n)\right) \qquad [14]$$

Luce's choice axiom receives support from numerous experiments in psychology and economics.

The majority of psychophysical theories and experiments focus on the ability to discriminate between stimuli rather than on the similarity between them. Shepard (1957, 1987, see Borg and Lingoes, 1987) proposed that similarity between two stimuli, (S_i, S_k), is a continuously changing negative exponential function of the distance, d_{ik}, between them. The probability of correctly identifying a particular stimulus from a set of n stimuli is often assumed to be

$$p_{ik} = \exp(-d_{ik})\Big/\sum_n \exp(-d_{in}) \qquad [15]$$

a form similar to Luce's choice axiom.

Following Thurstone's (1933) suggestion that there are many underlying psychological continua, Anderson (1981) proposed an information integration theory of how sensory values on different dimensions are combined to create perceptual experience. Anderson's cognitive algebra creates perceptual magnitudes from a linear model of sensory values defined on the dimensions on which a stimulus projects its values. Subjectively, a fine dinner is a sum of the psychological values of its many components.

The question as to how these complex stimuli are represented in a psychological space has moved beyond the earlier considerations of single dimensions to questions of whether multiple dimensions define a space in which stimuli are represented. Ashby and Townsend (1986) suggest ways to determine separability, independence, and orthogonality, while Suppes (2002) and Colonius and Dzhafarov (2006) provide deeper analyses of the necessary conditions for representations and issues surrounding multiple and infinite dimensional representation spaces. As psychophysics enters the twenty-first century, its applications in many areas of psychology and related disciplines are described in *Psychophysics Beyond Sensation* (Kaernbach et al., 2004).

Conclusion

During nearly 185 years, the field of psychophysics introduced new measurements of, and theories about, mental processes. Following Weber's discovery of the jnd, Fechner created Weber's law, the field of psychophysics, and a theory of error in sensory comparisons. Fechner's law, that the amount of sensation equaled a logarithmic transformation of the physical stimulus intensity, provoked continual controversy. Piéron showed that the time required to respond to the presence of a stimulus obeyed a power law of stimulus intensity. Stevens proposed that the amount of sensation obeyed a power law with an exponent unique to a sensory modality. Urban created the psychometric function as a means to determine accurately the 75% threshold. Thurstone introduced the idea of psychological continua on to which stimuli project psychological values. Comparisons between two psychological values led to the Law of Comparative Judgment and measurements of stimuli not defined on a physical scale. Anderson proposed a cognitive algebra for adding or multiplying psychological values combined across several such psychological continua.

However, cognitive factors were also shown to affect judgments of stimuli. Coombs proposed that psychological values were compared against ideals rather than against each other, and suggested a method of locating an ideal. The signal detection theory provided for a decision criterion that could vary in response to cognitive factors. The various ROC results previously requiring separate theories for their explanation were shown to follow from a sequential theory of psychological discrimination. Theoretical ideas suggested new experiments. New empirical discoveries challenged old theories. Relations between response probabilities, response times, and response confidence provided new ways to test theories. Now, at the beginning of the twenty-first century, psychophysics is poised for major theoretical advances toward more refined and more extensive measurements of mental processes as evidenced in *Measurement with Persons* (Berglund et al., 2012).

Psychosocial Work

Abstract

This article begins by defining the variously used term 'psychosocial' across disciplines, followed by an examination of its ambiguous position in social work. The dual-foci debate in social work provides the context for understanding the evolution of psychosocial work through time and applications. Eschewing the narrow conceptualizations related to psychopathology and trauma is a major shift in international psychosocial work, particularly in emergencies, to address issues of resilience, community, and cultural resources, wider social influences, and human rights. After presenting the emerging trends in the 'both–and' perspective in psychosocial work and reviewing research, ethics, and other critical issues, this article charts the future direction of psychosocial work.

Introduction

Psychosocial practice is one of the oldest, if not the oldest, professional practice framework in social work, and it has continued to evolve over time (Mattaini and Lowery, 2007). With a strong psychodynamic tradition to begin with, the approach gradually recognized the place of developmental processes over the life course, including environmental forces. Despite its legacy and evolution, psychosocial practice is not the most established or widely applied framework in social work. This is not unconnected to its vague conceptualization and varied definitions.

Definitions

Psychosocial work is an ambiguous concept in social work, though the term 'psychosocial' is commonly, and sometimes variously used to refer to a plethora of concepts and phenomena, such as psychosocial factors, psychosocial status, psychosocial support, psychosocial adjustments, psychosocial interventions, psychosocial contexts, psychosocial well-being, psychosocial effects, and psychosocial risks, with little consensus about what 'psycho' and 'social' entail. This is not unrelated to social work drawing knowledge heavily from the fields of psychology and sociology, and the new wave of psychosocial theory currently under construction in sociology, social policy, social research, and psychology. In sociology, the 'psycho' component of the term psychosocial often refers to psychoanalytically informed theory with its intellectual inheritance of critical theory. Though the 'social' component in social work traditionally referred to the context of interfamilial relations, it has more recently been extended to gender, culture, youth, and the reproduction and reinforcement of social stratifications from structural perspectives. (Cooper, 2000; Frost, 2008). This shift means greater focus on the social dimensions of structural issues, such as poverty, inequality, oppression, power in relationships (including relationships between the professionals and service users), moving away from the psychodynamic emphasis of the internal world and interpersonal processes.

In human development studies, which social work draws upon heavily, psychosocial development conventionally refers to change and stability in emotions, personality, and social relationships that can affect cognitive and physical functioning (Papalia et al., 2009). Deriving from the psychoanalytic tradition, Erik Erikson's (1950) seminal psychosocial development theory utilizes 'crisis' or conflicting tendencies in each of the eight stages as a major psychosocial theme throughout life. But critical psychologists are moving from psychosocial theory in a different direction beyond the psychodynamic tradition, and referring to social change to treat and prevent psychological problems (Frost, 2008; Kovel, 2011).

Currently, one of the most commonly quoted psychosocial definitions was developed by the World Health Organization (WHO). Since WHO (2003) defined health as a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity, it acknowledged that psychosocial interventions imply that social interventions have secondary psychological effects, and that psychological interventions have secondary social effects. Given this comprehensive definition, a wide range of international psychosocial programs are included. Some of the programs focus primarily on promoting and strengthening human rights and social justice issues, while others are more orientated toward community development; still others gravitate toward implementing therapeutic programs. Along this line, the Psychosocial Working Group (2003) (established in Oxford in the United Kingdom) reiterated that:

> The term 'psychosocial' is used to emphasize the close connection between psychological aspects of our experience (our thoughts, emotions and behaviors) and our wider social experience (our relationships, traditions, and cultures). These two aspects are so closely inter-twined in the context of complex emergencies that the concept of 'psychosocial well-being' is probably more useful for humanitarian agencies than narrower concepts such as 'mental health'. Interventions focusing narrowly on mental health concepts such as psychological trauma run the risk of ignoring aspects of social context that are vital to well-being. The psychosocial emphasis on social as well as psychological aspects of well-being also ensures that the family and community are fully brought into the picture in assessing needs. (p. 3)

The term psychosocial, regardless of its evolving definition, has offered an alternative paradigm that requires due consideration of both the 'psycho' and 'social' components, and does

not treat the two as an 'either/or' parallel. This calls for a shift to a more dynamic, interactive, and multilayered definition.

Psychosocial Work History, Theoretical Underpinnings and Leading Figures

Though Hamilton (1940) was among the first to use the term 'psychosocial,' Florence Hollis is widely recognized as the most authoritative in developing the psychosocial framework (Hollis, 1964; Woods and Hollis, 1990; Goldstein, 2008) and psychosocial therapy (Turner, 2009) in social work. Hollis' psychosocial framework emphasized the interface between the client and his or her environment. Traditionally, the framework integrated ecological and systems concepts with contemporary psychodynamic theories, including Freudian psychoanalysis, ego psychology, attachment and object relations theory, to understand the in-depth personalities and the coping capacities of individuals, couples, families, and groups in treatment (Woods and Hollis, 1990). Over time, it continues to evolve by incorporating psychological and social theories, as well as new perspectives related to gender, culture, and diversity. Grounded on this development, psychosocial casework is most widely associated with clinical social workers today (Goldstein, 2008). This development has generally continued to enjoy an important position in current social work and has flourished by emphasizing access and sensitivity to minority groups. But radical social work in the United Kingdom (Cooper, 2000) and structural social work that first emerged in Canada (Hick and Murray, 2013) have fiercely challenged psychosocial and clinical social work since the 1970s. They argued for mobilizing people as agents of social change and were strongly against encouraging conformity and adaptation to unequal power relations through casework (Cooper, 2000; Hick and Murray, 2013).

This long-standing argument on the focus of change in social work can be traced to the early roots of social work, and it is apparent that the development of the psychosocial framework can be better appreciated by reviewing the earliest origins of social casework (Kam, 2012). One of the earliest origins of social work is related to the legacies of the Charity Organization Society (COS) established in March 1870 in London, which aimed to provide principles to guide charitable giving and coordinate charitable organizations (Payne, 2005). COS members investigated and assessed whether applicants for assistance were deserving of help (Dominelli, 2004; Payne, 2005). This establishment rapidly spread to the United States especially in view of the immense social needs in the post–Civil War era. Mary Richmond could be considered one of the foremost pioneers in the United States, who advocated social change through improvement in the lives of individuals and families. She recognized that "mass betterment and individual betterment are inter-dependent; however, social reform and social case work of necessity progressing together" (Richmond, 1965: p. 25). Many proponents of clinical social work and psychosocial therapy have continued to defend their practice from a social justice perspective (e.g., McLaughlin, 2002; Parker, 2003) and have argued that a lopsided emphasis on the changing of environment may well end up in neglecting the psychosocial adjustments and well-being of poor and marginalized people. From the social justice perspective, Wakefield (1988) highlighted that psychological and emotional good health should not be restricted to the wealthy.

The other origin could be associated to settlements, which were founded as a movement for working-class education and the maintenance of moral Christian social behavior in poor neighborhoods. Along with relief of poverty, debate and campaigning on social policy was a part of the education activities in new cities (Payne, 2005). The first settlement was Toynbee Hall, founded by Canon Samuel Barnett in 1884 in the East End of London. As with the COS movement, the settlement idea was rapidly imported into the United States, and the first settlement was founded in New York in 1886. The famous Hull House in Chicago was formed in 1889, and one of its leaders, Jane Addams not only worked with the poor but also engaged in political action aimed at establishing new laws to protect them, and pioneered many social changes and reforms. She has been an important influence on the nature of social work (Payne, 2005). These crucial origins of social work has helped shape the contentious dual foci of change in social work today, which is unlikely to be resolved given its purpose to enhance adaptations among individuals, families, communities, or other collective entities within the ecological fields which they are embedded, consistent with social justice (Mattaini and Lowery, 2007).

In the global definition of social work jointly adopted by the International Federation of Social Workers (IFSW) and the International Association of Schools of Social Work (IASSW) in 2001 (each organization had worked on it for several years previously and adopted it separately in 2000), the dual foci of the interaction between the two separate and interactive entities of the environment and the individual was further augmented, in that "Social work intervenes at the points where people interact with the their environments" (IFSW, n.d.). Moreover, the definition's emphasis on the principles of human rights and social justice, articulated clearly the meaning and purpose of social work. Therefore, it is not the particular strategy of changing the individual and/or social reforms, but ultimately attaining the fundamental goal of promoting human right and justice that makes the profession unique, with due respect to varying social, cultural, and political contexts. Highlighting social justice in social work practice further enriches the dual-foci discussion as the profession has always involved both 'cause' (the organized effort to advocate for oppressed populations) and 'function' (a set of direct-practice activities carried out with the sanction of the larger society) (Lee, 1929). The distinction and balance between the two dimensions have ebbed and flowed and has been an ongoing tension within the profession since its beginning (Mattaini and Lowery, 2007). As Payne (2005) poignantly pointed out:

> Social workers will always be dealing with change…. The balance at any time and in any situation between social order and caring, between the state and the individual and between male administrative power and female caring power will be played out in their practice. (p. 247)

Between meeting individual needs and engaging in social changes, some social workers believe that the "middle ground, if one ever existed, is quickly receding. Social workers must decide on which side they stand" (e.g., Abramovitz, 1998: pp. 524–525). But this article suggests that the profession needs to duly consider the dual foci of 'psycho' and 'social' within the social justice framework to best serve the clients that include individuals, families, groups, and communities. The following sections review the application of psychosocial work in different settings in the United Kingdom, the United States, and international emergency situations, with focus on the distinction and interaction between the 'psycho' and 'social' dimensions.

Current Psychosocial Work Applications

Walker (2004), moving away from the arbitrary division of social work orientations, presented a modern psychosocial model of social work, particularly in working with children in the United Kingdom. His flexible model was community-oriented, service-user influenced, and took into account "the relationship between the external social world and the inner psychological experience of the individual that caused some citizens pain and suffering" (p. 163). He called for the consideration of both the inner and outer world of service users, especially those who had to contend with poverty, marginalization, social exclusion, and racism in established minority communities and those traumatized by war, ethnic persecution, and disasters. Intervention at one level included work carried out with individuals, families, and local networks to tackle problems that directly affected them. At another level, interventions also included advocacy and social action with community groups and other professionals and agencies to tackle problems affecting a range of people. Moreover, this modern psychosocial model offered social work a framework to engage both the professionals in the community as well as to collaborate with the service users. This holistic model envisaged that individual therapeutic or micro-interventions that focused on individual or family problems can also contribute to wider social transformation in neighborhoods, and conversely, in community practice that can also enable personal change and growth in individuals through social action and the fostering of cooperative capacity. However, community-based psychosocial and mental health care is not without its constraints and setbacks. Rose (1996) identified three broad defining features of community care that set it apart from earlier phases of mental health care. Sawyer (2008) referenced these features to highlight the constraints of community-based mental health services in Australia: (1) greater involvement with other agencies, which means that a higher level of communication and coordination is demanded among more stakeholders – this could be rare; (2) neoliberal norms of personal responsibility, choice, and empowerment, which implies that service users are encouraged to 'take responsibility' for themselves through learning about their illnesses and discouraging them from becoming too dependent on the given service; (3) and a culture of accountability and blame, in which someone must be held accountable. These three features have heightened mental health professionals' consciousness of risk and evoked concern to protect their professional integrity.

In the USA, psychosocial (or psychiatric) rehabilitation (United States of America Psychiatric Rehabilitation Association (USPRA), n.d.) promotes recovery, full community integration, and improved quality of life for persons who have been diagnosed with any mental health condition that seriously impairs their ability to lead meaningful lives. While its services are collaborative, person-directed, and individualized, the focus is on helping individuals develop skills and access the resources needed to increase their capacity to be successful and satisfied in the living, working, learning, and social environments of their choice. Taintor (2008) considered social workers as especially well qualified to work on the psychosocial multidisciplinary treatment teams because they have a mixture of skills and support for persons severely impaired by mental illness. Specifically, social workers are well trained to work with community organizations and to help service users obtain social support, and are trained to assist them through counseling and skills development. Moreover, social workers are used to working with their strengths, and advocate for their rights to be socially included and be treated as another individual in the society. Such an orientation has also been found to be relevant in promoting the strengths and rights of individuals affected by disasters and emergency settings recently, and the next section will tracks its recent developments with different client groups across cultures (Arntson and Knudsen, 2004; Kos and Zemljak, 2007; Ehrenreich, 2001; Lith, 2007; North Atlantic Treaty Organization (NATO), 2008).

Shifts in International Psychosocial Work: Promoting Resilience and Community Resources

Posttraumatic stress disorder (PTSD) has commonly been used as the predominant lens to implement interventions with individuals and populations affected by disasters. But there are several setbacks. First, PTSD is only one of the many psychological and social problems after a disaster. Secondly, only a small proportion of people may suffer from PTSD and acute distress, both immediately and in the long term, while the majority may have a range of other needs and situations, including those who may not need clinical interventions, such as physical and mental exhaustion, acute stress, and anxiety from being separated from family members (Arntson and Knudsen, 2004; Bourassa, 2009; Inter-Agency Standing Committee, 2007). Thirdly, psychological distress and trauma have a social and cultural dimension. The ensuing interventions recommended for individuals diagnosed with PTSD may unfortunately not be culturally appropriate. For instance, immediately after the Wenchuan earthquake in Sichuan of China in May 2008, there was a widespread dictum: Run away from dogs (that may be been infectious after the earthquake due to poor hygiene), run away from fire (due to the close proximity of makeshift housing), and run away from psychotherapists (who may do harm). This dictum was a culmination of many earthquake survivors being subjected to a 'second disaster' when international aid agencies, local psychologists and psychotherapists, academics

and well-meaning volunteers went around conducting culturally irrelevant psychotherapeutic assessments and interventions (Sim, 2009). Last but not least, privileging the pathological lens inevitably implies that social and political contexts and processes that occur and endure over extensive periods of time may be unduly neglected. Pupavac (2001) raised two specific concerns when psychosocial interventions in emergency settings focus on individuals' deficits and pathology. First, individual rights are being reconceptualized in psychological terms. This may lead to individuals being protected by official bodies, rather than protection from official bodies in some disaster or conflict situations. For example, understandably anxious, tired, or depressed survivors in post-disaster situations are being pathologized as unable to function by public health professionals. As a consequence of the pathologization of their condition, psychosocial intervention implicitly denies the capacity of populations to negotiate with the authorities about their well-being and even participate in the post-disaster reconstruction process. Second, psychosocial initiatives may potentially erode community and family cohesion. External and professional intervention may unwittingly undermine the sense of intimacy necessary for communal and family bonds. Moreover, such interventions encourage identification with and dependence on professional bodies thereby corroding local ties and institutions. This shift in focus away from pathology is also evident in psychosocial work with children internationally. Instead of focusing on remedial psychosocial interventions that put individual problems center stage, developmental approaches that capitalize on community resources are recommended. For example, the United Nation Children's Fund (UNICEF, 2007) argued that an important aim of all psychosocial support activities should be the strengthening of the capacity of families to nurture and support their children at the household level, as well as fostering of the social networks that would normally sustain mothers and fathers in emergencies. The United Nations High Commissioner of Refugees (UNHCR, 2004) in its guidelines on protection and care for refugee children indicated that the best way to promote the psychosocial well-being of children is to support their families and communities, and highlighted the role of schools in providing structure and predictability. International humanitarian and development agencies such as Save the Children (Arntson and Knudsen, 2004) and the International Rescue Committee (IRC, 2003) published similar recommendations, while taking into consideration the rights of children. Several arguments are apparent for a developmental psychosocial approach in work with children: only a small portion of young persons sustain serious psychological problems requiring specialized care in disaster and emergency situations; Western mental health therapies based on trauma and related mental pathological classifications are not suitable in culturally different settings; and the well-being of children often depends on secure family relationships and a stable environment with strong social support and social ties (Arntson and Knudsen, 2004; Duncan and Arntson, 2004).

Garcia del Soto (2008) highlighted the use of the term 'community approaches' in psychosocial work to contrast to individual approaches to mental health (p. 228). Such a shift in perspective highlights the need to promote the individual's trust about living in his or her community and society, apart from the challenge to promote individual resilience to maintain control of life in emergency situations. There is, therefore, a need to design and implement programs in ways that make sense to local populations by respecting their contexts. This requires not only consideration of socio-economic, political, generational, gender, spiritual, ethnic, and cultural practices, but also reinforcement of existing resilient resources within the community in the face of adversity (Duncan and Arntson, 2004; Lith, 2007; NATO, 2008; Tol et al., 2011). As Ehrenreich (2001) aptly reasoned, the individual and community approaches are not really in opposition to one another. The healing and rebuilding of the community is an essential underpinning for the healing of individuals and families, and the healing of individuals and families is necessary for the successful reconstruction of the community. In each case, the underlying principle is to encourage healing processes, in individuals, families, and communities. Thankfully, the perennial struggle between the two foci of change in social work has provided a fluid imagination for the profession, and nurtured an inclusive and flexible culture that allows the profession to include a rich and diverse set of skills, knowledge, and forms of practice (Yan et al., 2012).

The Inter-Agency Standing Committee (IASC) worked out a set of guidelines on mental health and psychosocial support in emergency settings (IASC, 2007) to facilitate an integrated approach to address the most urgent mental health and psychosocial issues in emergency situations. It addresses the social risk factors that affect mental health and psychosocial well-being that most mental health professionals seldom work in, including disaster management, human rights protection, general health, education, water and sanitation, food security and nutrition, shelter, camp management, community development, and mass communication. The set of guidelines recognizes that mental health and psychosocial problems in emergencies encompass far more than the experience of PTSD and not everyone has or develops significant psychological problems during an emergency. On the contrary, the guidelines capitalize on the fact that many people show resilience, that is, the ability to cope relatively well in situations of adversity. More importantly, attention is given to numerous interacting social, psychological, and biological factors that affect people in developing psychological problems or exhibiting resilience in the face of disasters. The IASC (2007) reiterated that a 'common error' in work on mental health and psychosocial well-being is to ignore the resources of different age, gender, socio-cultural context, and the emergency environment, and to focus solely on deficits – the weaknesses, suffering, and pathology – of the affected group (p. 4). Examples of potentially supportive social resources include families, local government workers, teachers, women's groups, youth clubs, and community planning groups, among many others. Affected communities may have economic resources such as savings, land, crops and animals; educational resources such as schools and teachers; and health resources such as health posts and staff; significant religious and spiritual resources including religious leaders, local healers, practices of prayer and worship, and cultural practices, such as burial rites. Increasingly, more social workers have used the individual-environment

perspective, due to its flexible and open nature, to develop antioppressive and culturally sensitive practices in international psychosocial work, particularly in emergency settings and humanitarian work (Bourassa, 2009; Ehrenreich, 2001; Frost, 2008). These shifts in perspectives and strategies correspond well with the dual-foci debate in social work, which allow social workers to be at the forefront of emergency and humanitarian aid at local and international levels. But the question of whether general psychosocial guidelines are in line with social work values, ethics and best practices remain to be researched in depth. Moreover, when applying or exporting them to different communities, both social work and general psychosocial principles may contradict the unique local characteristics. The need to engage with local groups and local professionals so as to be relevant and respectful cannot be overemphasized.

Emerging Trends and Directions

There is a recent call to end the debate between the two foci of 'psycho' and 'social' and to accept a two fold approach tailored to the specific needs and strengths of individuals in the respective contexts (Loughry and Eyber, 2003). While developmental responses are regarded as the most appropriate as generic types of interventions, curative methods are said to be useful to a smaller group of people, such as children who are extraordinarily affected, or those who have not benefited from generic interventions. Specifically, 'a stepped model' whereby the needs of the individuals are assessed according to levels may be useful. For example, Save the Children adopted the approach of disaggregating children in emergencies to three groups according to needs: the severely affected group, the 'at-risk' group, and the generally affected group (Arntson and Knudsen, 2004). The severely affected group is often expected to be a small percentage of children whose psychosocial functioning may be severely compromised. They would benefit from individualized treatment. The at-risk group is expected to be larger than the severely affected one and consists of those who have experienced severe losses and disruptions. They may be significantly distressed, despairing, and hopeless, but their social and psychological ability to function has not yet been overwhelmed. Without timely community and social support, their psychosocial functioning may be at risk of deteriorating. Short-term crisis interventions and support groups may be useful interventions for this group. The generally affected group refers to the broadest segment of the population who may not have been directly affected though they may be disturbed or stressed. Over time, this group will become better even without direct support. Prevention, structured activities, and normalization may suffice for this group of people. This stepped model is useful in meeting the varying needs of affected individuals, and at the same time helps to engage different professionals or provide different types of services according to the needs of affected groups. In the aftermath of a population's exposure to severe stressors, the WHO advocated a focus on medium- and long-term development of community-based and primary mental health care services and social interventions as they are much more effectively implemented over a protracted time during subsequent years. Unfortunately, impetus and funding for mental health programs is highest during or immediately after acute emergencies and not for medium- and long-term programs (WHO, 2003).

When working with children, young people, women, families, and special groups in varying contexts, the focus of change should not be that of 'either/or,' but 'both–and' according to the context of needs, as feminist social work has promulgated (Brandwein, 1986; White, 2006). Dominelli (2002) has updated 12 feminist principles as relevant to practice and evident in feminist social work. The following are a few principles that echo the discussion on the dual focus of change in psychosocial work:

- recognizing the diversity of women;
- valuing women's strengths;
- locating individual women in their social situations and acknowledging the interconnections between the individual and collective entities relevant to them;
- acknowledging that the principle, 'the personal is political' is relevant at macro-, meso-, and micro-level of practice;
- redefinining private woes as public issues;
- recognizing that women's individual problems have social causes and addressing both levels in each intervention; and
- looking for collective solutions to individual problems (Dominelli, 2002: pp. 162–163).

These feminist social work principles help to reconcile the tensions between the individual and social by suggesting that the personal, individual, and private experiences are a legitimate focus for, and site of, political action (Orme, 2013). While this duality of focus and the mission to pursue human rights and social justice set social work apart from other professions, 'psychosocial work' can be considered a term that encapsulates the dual strategies of the profession. It also reflects the need for social workers to continually consider the different foci of change when working different groups.

Critical Issues in Psychosocial Work

Psychosocial work has rather limited quantities of and in quality research. Tol et al.'s (2011) comprehensive review of mental health and psychosocial support in humanitarian setting concludes that there is little link between practice and research. Specifically, research is infrequently implemented. Existing outcome assessments have focused predominantly on PTSD, though there is still disagreement about the public health value of this disorder. Psychoeducation, structured social activities, and counseling had been frequently practiced but were included in few evaluation studies that often presented mixed results. However, limited and mixed results do not necessarily indicate that these approaches are not effective. Rather, these point to the need for more rigorous examination. In the quest for more evidence, psychosocial workers and researchers ought to be mindful of the impact of evaluation and research on the people affected by disasters and crises that they endeavor to serve and understand. Some evaluation methods may not be appropriate for some socio-cultural contexts (Ehrenreich, 2001; Kos and Zemljak, 2007; Lith, 2007; WHO, 2003). For example, in India, Pakistan,

and Jordan, local workers trained in North America or Europe could not translate the term 'psychosocial' into Hindi, Urdu, or Arabic for monolingual populations because theories from other fields such as religion or political science prevail regarding the individual's relationship to society (Aggarwal, 2011). And, the evaluation of psychosocial work, within a short frame of time given the complexity of contexts and issues involved, may be arduous.

Conclusion

Psychosocial work embodies the long-standing dual-foci debate in the social work profession that has instrumentally allowed the highest flexibility for the profession to negotiate its roles and tasks with different stakeholders, domains, and contexts. Due consideration of the balance offered by the dual-foci approach has opened up possibilities for the profession to include a diverse set of values, knowledge, and skills of practice. Careful deliberation of the interaction between the 'psycho' and 'social' dimensions highlight the need to consider salient perspectives in social work, including but not limited to 'both–and' and 'either/or,' resilience and pathology, past and present, the inner and outer worlds of service users, foreign and local contexts, the individual and community resources of different service users, and the settings they are in. When carrying out psychosocial work, social workers who promote human rights and social justice would reveal a marked difference from other professional groups.

Abstract

Psychosomatic medicine focuses on holistic care, involving the biopsycho-social aspects and mind–body relationships. It involves the role of psychosocial factors in etiopathogenesis and maintenance of medical conditions, and the importance of holistic interventions. The term psychosomatic medicine has undergone transformation following the growing rejection of psychodynamic and psychoanalytic schools of thought and replaced by contemporary concepts of consultation liaison psychiatry, behavioral medicine, and general hospital psychiatry. The role of stress and neurohumoral activity still remain of importance, and behavioral and alternative medicine gain significance. Diagnostic criteria for psychosomatic research have been proposed and methodologically stringent studies are needed to validate the concepts of psychosomatic conditions.

Concepts

The term 'Psychosomatic' has been used in several ways and various definitions have been put forth. Not only has this term been in dispute but the field of psychosomatic medicine itself has often been rife with ambiguity and controversy, due to various reasons.

Psychosomatic medicine provides a comprehensive framework for a holistic (biopsycho-social) consideration of patient care encompassing: (1) the role of psychosocial factors in affecting individual vulnerability to all types of diseases; (2) the interaction between psychosocial and biological factors in the course and outcome of disease; and (3) the application of psychological therapies to the prevention, treatment, and rehabilitation of physical illness (Fava and Sonino, 2000).

Modern psychosomatic medicine originated in the developed Western world, but it is equally relevant to all nations. In the areas of clinical practice and the training of health workers, psychosomatic postulates regarding comprehensive care of patients and the behavioral aspects of prevention of disease are just as applicable in developing as in developed countries.

Psychosomatic medicine arose from the psychodynamic theory and practice in the twentieth century, and referred to the concept that psychological factors are important in the etiology and course of certain physical/medical disorders. It became influential in the 1930s in the United States and in the German-speaking countries. It continued to flourish in parts of Europe, as a medical specialty, which was different from both internal medicine and psychiatry. In other parts of the world, it did not become popular after the 1960s. Outside German-speaking countries, psychosomatic theory is not popular and not seen as useful. The emphasis on the interaction of physical and psychological process is beneficial, but a simplistic assumption about possible psychological factors affecting physical disorders is a bit difficult to accept and understand. Psychosomatic medicine has had a lasting legacy within medicine in promoting greater understanding of psychological aspects of physical symptoms and disorders (Mayou, 2008).

The psychosomatic approach has explored linkages between psychological and neurophysiological processes influencing health and disease. The largest share of current psychosomatic research focuses on mediation by the brain from relationships between behavioral traits and disease state. The advent of the cognitive neuroscience methods has ushered in a new era in which the brain basis of mental states relevant to psychosomatic medicine can begin to be identified. Investigators in psychosomatic medicine should support their theoretical models and empirical investigations by including further consideration of the brain and mind–body interactions (Lane et al., 2009).

Alternative Terminology

Psychosomatic medicine has now been replaced by terms like consultation liaison (C-L) psychiatry, behavioral medicine, health psychology, and general hospital psychiatry.

Behavioral medicine is an interdisciplinary field concerned with the development and integration of behavioral and biomedical science knowledge and techniques relevant to health and illness and the application of this knowledge and these techniques to prevention, diagnosis, and rehabilitation.

C-L psychiatry is the study, practice, and teaching of the relation between medical and psychiatric disorders. The psychiatrists as consultants play many roles: interviewer, therapist, teacher, physician as part of the team, diagnosis, and treatment. Principal contribution to medical treatment involves a comprehensive analysis of a patient's response to illness, psychological and social resources, coping style, and psychiatric illness.

Consultation psychiatry refers to individuals trained as psychiatrists providing consultations to colleagues from other medical specialties upon receiving a specific referral. Occurring both in inpatient and outpatient settings, the consultation is

limited to evaluating the referred patient for psychiatric symptoms and suggesting a plan of management. It involves limited interaction with the referring physician. The psychiatrist is usually not involved in the day-to-day care of the patient.

Liaison psychiatry is a much closer integration of psychiatric services with the medical services. Typically occurring in the inpatient setting, it involves a physician or psychiatrist (the C-L psychiatrist) being a part of the medical team and seeing all patients under their care irrespective of presence of psychiatric symptoms or referral.

C-L psychiatry's growth continued as a specialization in cancer units, ICUs, burns, dialysis, obstetrics and gynecology, pediatrics, cardiology, neurology units, reaching nonreferred populations by screening and triage methods. Liaison psychiatry encompasses clinical, teaching, and research activities of psychiatrists in the nonpsychiatric divisions of general hospitals. The Liaison psychiatrist seeks to enhance the psychological status of all the medical patients, aims to participate in case detection rather than waiting for referral and provides educational programs (Chaturvedi and Tipirneni, 2005; Chaturvedi and Jaideep, 2007).

There has an upsurge of interest in another related discipline, subsumed under the rubric of mind–body interrelationships, sharing the same holistic, biopsycho-social connotation with psychosomatic medicine. However, the concept of mind–body medicine is inextricably linked to that of alternative therapy (Pert et al., 1998). Psychosomatic medicine continues to manage patients in medical settings that cut across a continuum from primary care to complex medical and surgical centers. The clinical problems containing a medical–psychiatric interface offer a clinical challenge and an area for new knowledge and better interventions (Wise, 2008).

Criticisms of the Term 'Psychosomatic'

The term 'psychosomatic disorder' was strongly criticized by several psychosomatic researchers. Lipowski (1986) criticized the obsolete notion of psychogenesis, since it was incompatible with the doctrine of multicausality, which constitutes a core postulate of current psychosomatic medicine. Engel (1967) wrote that the term 'psychosomatic disorder' was misleading, since it implied a special class of disorders of psychogenic etiology and, by inference, the absence of a psychosomatic interface in other diseases. On the other hand, he viewed reductionism, which neglected the impact of nonbiological circumstances upon biological processes, as a major cause of mistreatment (Fava, 1992). Tinetti and Fried (2004) suggested abandoning disease as the primary focus of medical care. When disease became the focus of medicine in the past two centuries, the average life expectancy was 47 years and most clinical encounters were for acute illness. Currently, the life expectancy in many developed countries is much higher and most of clinical activities are concentrated on chronic disease or nondisease-specific complaints. As time went by, psychosomatics gained a rather broader connotation and refers to the study and treatment of those conditions, which are related to the interaction of psychic and somatic phenomenon. The various categories of clinical phenomenon included in psychosomatic medicine thus defined, are enumerated below:

1. Psychological reactions to physical illness, surgical procedures, radiation therapy, etc., like emotional and behavioral responses to physical illness.
2. Disturbances resulting from disorders affecting brain function, acute or chronic organic brain syndromes.
3. Medical complications of maladaptive behavior, like alcohol and drug abuse, obesity, eating disorders like anorexia and bulimia.
4. Emotional disorders manifested by somatic symptoms with no organic basis or functional somatic symptoms or medically unexplained symptoms, e.g., somatoform disorders, neurotic disorders, masked depression, conversion disorder, hypochondriasis, chronic pain, chronic fatigue, etc.
5. Physiologic concomitants of emotional states.
6. Psychosomatic diseases, the classical psychosomatic disorders like hypertension, bronchial asthma, rheumatoid arthritis, ulcerative colitis, neurodermatitis, duodenal ulcer.
7. Physical illnesses presenting as emotional or psychological problem, e.g., myxedema, thyrotoxicosis.
8. Psychological adverse drug reactions to drugs used for medical illnesses, e.g., steroids, antihypertensives.

Both psychophysiological and psychosomatic disorders are associated with prolonged psychological stress. Some of the important psychosomatic disorders, psychophysiological symptoms and functional somatic symptoms areas follows:

Physiological somatic system	*Psychosomatic syndrome*	*Psychophysiologic symptom*	*Functional symptom*
1. Cardiovascular	Coronory heart disease Essential hypertension	Migraine headache Vasovagal syndrome Tachycardia Palpitations	Noncardiac chest pain
2. Gastrointestinal	Peptic ulcer Ulcerative colitis Mucous colitis	Irritable colon Psychogenic vomiting Aerophagy Abdominal cramps	Irritable bowel syndrome
3. Genitourinary pain	Dysmenorrhoea Premenstrual syndrome Female 'Dhat' syndrome	Psychogenic impotence Dyspareunia Anorgasmia	Chronic pelvic
4. Musculoskeletal	Rheumatoid arthritis Low-back pain	Psychogenic torticollis Muscle tension, pain, fatigue, tremor	Fibromyalgia Repetitive strain injury
5. Respiratory	Bronchial asthma	Hyperventilation Bronchospasm Hiccup (psychogenic), yawning, air hunger	Hyperventilation syndrome

Continued

Physiological somatic system	*Psychosomatic syndrome*	*Psychophysiologic symptom*	*Functional symptom*
6. Skin	Urticaria Dermatitis Eczema	Pruritus Hyperhidrosis	
7. Miscellaneous	● Chronic pain syndromes ● Obesity ● Anorexia ● Bulimia		

Other functional somatic symptoms, by specialty, are as follows:

Dentistry – atypical facial pain, temporomandibular joint dysfunction, burning mouth syndrome.
Ear nose and throat – Globus syndrome.
Neurology – tension headache.
Nonallied FSS – Gulf war syndrome, chronic whiplash, sick-building syndrome, candidiasis hypersensitivity, organophosphate poisoning, and multiple chemical hypersensitivity (Page and Wesseley, 2008).

The diagnosis of psychophysiological and psychosomatic disorders is done by the following:

1. The presence of symptoms and signs characteristic of a particular syndrome. Appropriate interview technique should elicit psychological symptoms in first contact.
2. The exclusion of organic disease through appropriate physical examination and laboratory procedures.
3. The presence of chronic stress, tension, episodes of anxiety, and/or stressful life situations, like exit life events, separation or death.

Diagnosing Psychosomatic Disorders

Psychosomatic disorders must be diagnosed precisely and must be distinguished from physical illnesses, somatoform disorders, hypochondriasis, conversion disorders, and other psychiatric illnesses with somatic presentations.

Certain characteristics of psychosomatic patients are as follows:

1. They present to physician, invariably.
2. May have inherited or early acquired (through illness or conditioning) organ or system vulnerability.
3. Evidence of chronic and sustained emotional or autonomic arousal on response to stress.
4. Precipitating life events could be identified.
5. Certain personality traits, like type-A personality for coronary heart diseases.
6. Difficulty in expressing feelings and emotions, have affective inhibition and alexithymia.
7. Poor psychological mindedness or sophistication.
8. Show abnormal illness behavior in the form of disease conviction, somatic preoccupation, somatic attribution, somatic focusing, nonresponse to reassurance and a need to deny psychological component.

Classification of Psychosomatic Disorders

The third edition of Diagnostic and Statistical Manual of Mental Disorders (DSM-III) introduced somatoform disorders as a speculative diagnostic category. It remained in the successive versions of DSM-III-R and DSM-IV. Somatic syndromes that were neither explained by a general medical condition nor clearly associated with depressive or anxiety diagnoses were combined to create a new category of somatoform disorders. In the subsequent revisions of DSM-III, minor changes to the definitions of these disorders were made. There was also one major change, which was the introduction of undifferentiated somatoform disorder. The addition of this new diagnosis was necessary to categorize the large number of patients who, although clearly ill, did not fall within the existing somatoform categories. As a result, the category of somatoform disorders changed between DSM-III and DSM-IV from being a small grouping of relatively uncommon conditions to a general category covering a wide range of illnesses. The tenth revision of International Classification of Diseases (ICD-10) was developed in parallel with DSM-IV and also includes a similar, but not identical, category of somatoform disorders embedded within the broader "Neurotic, stress-related, and somatoform disorders 'category'" (Mayou et al., 2005).

Proposals for DSM-V/ICD-11

The DSM-IV-TR category of somatoform disorder introduced ambiguity into the classification of 'Specialty' syndromes such as irritable bowel syndrome (IBS), and fibromyalgia (FM). Such syndromes are characterized by medically unexplained physical symptoms and are found in many different medical specialties, such as IBS in gastroenterology, and FM in rheumatology.

The unifying principle for the category, the feature that the somatic symptoms are 'medically unexplained' is highly unsuitable as the unifying principle for a category of mental disorder. Hence, elimination of any reference to the physical symptoms of being 'medically unexplained' has been proposed in the forthcoming classifications (Sykes, 2012). Further, if a positive psychological criterion is provided, this will overcome the limitations of a negative diagnosis based on the feature of the physical symptoms being medically unexplained.

The diagnostic category of somatoform disorders is currently under revision for DSM-5 and ICD-11. In the current diagnostic draft of DSM-5, somatic symptom disorder includes the former diagnoses of somatization disorder, undifferentiated somatoform disorder, pain disorder, and partly hypochondriasis. It introduces two major changes in comparison with DSM-IV: First, the criterion of somatic symptoms is no longer limited to medically unexplained symptoms, thus eliminating the contentious and unreliable distinction between medically explained and medically unexplained symptoms as well as an implicit mind–body dualism. Second, positive psychological diagnostic criteria are added to the diagnosis,

which covers excessive thoughts, feelings, and behaviors related to these somatic symptoms or associated health concerns. Disproportionate and persistent thoughts about the seriousness of one's symptoms, a persistently high level of anxiety about health or symptoms, and excessive time and energy devoted to these symptoms or health concerns are other descriptions, which should persist for more than 6 months (Voigt et al., 2012).

Historical Aspects

The word 'psychosomatic' was first used in medical literature by Heinroth in 1818, though it may not have meant what it came to be considered a century later. Later, in 1922, Felix Deutsch introduced the term psychosomatic medicine, and in 1935, Dunbar described psychosomatic interrelationships in medical practice. This resulted from the confluence of two concepts having an ancient tradition in Western thought and medicine: those of psychogenesis of disease and of holism (Lipowski, 1986). The concept was formalized in 1939 by the editors of the journal *Psychosomatic Medicine*, a journal which is still a popular one dealing with 'biopsycho-social' and more aspects of health.

The idea of psychogenesis characterized the first phase of the development of psychosomatic medicine (1930–60) and resulted in the concept of psychosomatic disease (a physical illness believed to be caused by psychological factors, such as peptic ulcer). Diseases regarded previously as obscure of origin, had found an explanation and the prospects of treating them by psychotherapy appeared exciting. However, these expectations did not survive the test of scientific evidence and led to profound crisis (Wittkower, 1974). The identification of helicobacter pylori and its association with gastric and duodenal ulcers dumped the psychosomatic and psychogenic etiology of peptic ulcers!

Engel developed a multifactorial 'biopsycho-social' model of illness. It allows illness to be viewed as a result of interacting systems at the cellular, tissue, and organismic, interpersonal, and environmental levels. As a result, the study of every disease must include the individual, his body and his surrounding environment as essential components of the total system (Engel, 1967). Engel formulated a sharp criticism of the concept of disease as what can be understood and recognized by the physician, and proposed a unified concept of health and disease that was later elaborated upon within the biopsychosocial approach. Lipowski (1977) gave an invaluable contribution in setting the scope, mission, and methods of psychosomatic medicine. He identified three interrelated facets:

1. It is a scientific discipline concerned with the study of the relationships of biological, psychological, and social determinants of health and disease.
2. It embodies a holistic approach to the practice of medicine.
3. It encompasses C-L psychiatry.

Kissen (1963) provided a better specification of the term psychosomatic. He clarified that the relative weight of psychosocial factors may vary considerably from one individual to another within the same illness and underscored the basic conceptual flaw of considering diseases as homogeneous entities. Instead of asking, 'Which psychological factors give rise to which illnesses?' Kissen suggested asking, "who are the patients within a given illness population for whom psychosocial variables are of primary significance?"(Fava and Sonino, 2000).

Psychosomatic Disorders

Psychosomatic disorders or conditions that involve a major interaction of the mind–body interrelationships, occurring in different physiological systems can be described as follows.

Cardiovascular System

Psychocardiology is the study and practice of psychiatric aspects of cardiac disorders. Hypertension and coronary heart diseases are the common psychosomatic disorders seen in medical clinics and are frequently referred to psychiatrists for management of the psychological distress and psychiatric reactions. Hypertension may result from a variety of factors including psychological and emotional stresses. Though in the persistent and the more pathological varieties, the evidence of psychological factors is not quite so obvious and has given rise to considerable controversy.

Coronory heart disease (CHD, Ischemic heart disease (IHD)) like Angina Pectoris and Myocardial infarction are the two commonly encountered coronary heart disorders, where emotional and psychological factors have been implicated. Many studies have isolated a type-A behavior pattern, which has an overt style and has features of hard driving, competitiveness, impatience, sense of time urgency, and intensely committed to vocational goals. Other risk factors that have been identified in major collaborative studies are: high serum cholesterol, elevated systolic blood pressure, and cigarette smoking. Common reactions after a myocardial infarction include anxiety, depression, worry about future capabilities and sexual functioning, and hypochondriacal features.

Advancing technologies of cardiac catheterization, bypass surgeries, angioplasty, artificial heart valve surgery, atherectomy, cardiomyoplasty, stent procedures, transmyocardial revascularizations are likely to be associated with anxiety, health worry, and psychological reactions in the patients and their caregivers, which would need to be addressed by the C-L psychiatrists.

Gastrointestinal System

The most common focus for psychophysiologic and psychosomatic disorders was believed to be the gastrointestinal tract since it was thought to be associated with the symbolic expression of emotion through out life, starting from nursing in infancy and proceeding to toilet training. Medically unexplained symptoms related to the gut have been the most challenging. Peptic ulcer and dyspepsia have multifactorial etiology and the role of psychosocial factors is quite important. In Ulcerative Colitis, stressful psychological conditions had been observed as potential etiologic agents in most cases especially as separation, loss of love object, painful life situations, and life dissatisfaction. The principal etiologic factors are not known, however, psychological factors are thought to be important.

Respiratory System

The common cold, allergic rhinitis, and many cases of pharyngitis are thought to have a psychosomatic etiology. Bronchial asthma is the most serious psychosomatic disorder of this system. Bronchial Asthma is one of the commonest and most challenging of the psychosomatic disorders and has attracted considerable attention to its psychological and physical components. The specific role of psychological factors and psychotherapeutic interventions is debatable. The hyperventilation syndrome is found both in children and adults and may be initiated as a voluntary act, though in many instances it is a result of anxiety. It may not be recognized as such, for most do not present with respiratory distress, but with the physical sequalae of the hyperventilation. Other respiratory conditions considered as psychosomatic include psychogenic dyspnoea, allergic rhinitis, and the common cold.

Oncology

Psychooncology is the study of psychological, social, and environmental factors in relation to cancer, which have been implicated in the development, course, terminal phases, and consequences of cancer. This has been perhaps the fastest growing specialty on almost all aspects of cancer biology, disease, and treatment. The journal Psycho Oncology run by the International Psycho Oncology Society is a rich source of developments in this field.

Nephrology

Psychonephrology deals with the study of psychological and emotional aspects of renal diseases. Patients who develop end stage renal disease are not as a group predisposed to psychopathology and have low incidence of severe psychiatric disorder. They may develop maladaptive styles of coping with illness and thus present difficult problems for the staff such as noncompliance.

Dermatology

Psychodermatology is the study of psychosocial factors related to skin conditions like dermatitis, eczema, and urticaria, which are considered to have psychological and emotional factors involved in their causation and outcome.

Obstetrics and Gynecology

Psycho gynecology involves the study of numerous conditions, which have important mind–body interrelationships like premenstrual syndrome, postpartum disorders, pelvic pain, and perimenopausal disorders.

Somatizing Patient in Medical Clinics

All patients presenting with somatic complaints or chronic pain to physicians do not have physical disease. In fact, a sizable proportion of the medical practices of most physicians consist of patients for whom no objective evidence of a pathophysiologic process can be established. The prevalence of somatizing behavior is highest when the type of medical practice studied includes patients who complain of vague, poorly differentiated, or nonspecific symptoms. Medically unexplained/functional somatic symptoms are considered to have an unidentified interplay of body–mind mechanisms, with more role of the mind on the body, than vice versa!

Management of Psychomatic Disorders

Assessment

A considerable body of evidence has accumulated in psychosomatic medicine related to concepts such as quality of life, stressful life events, somatization, illness behavior, and personality, but it has not resulted in methods whereby psychosocial aspects of medical disease could be routinely assessed. The Diagnostic Criteria for Psychosomatic Research (DCPR) has been proposed to deal with the lack of specificity of earlier descriptions. The DCPR attempts to translate psychosocial characteristics observed in various medical diseases. The DCPR have now undergone extensive validation and have been found to be more suitable than DSM criteria in describing psychological distress in a variety of medical settings (Porcelli and Sonino, 2007).

The DCPR are a set of 12 psychosomatic syndromes whose prognostic role in the development, course and outcome of physical diseases, regardless of their 'organic' or 'functional' nature, was documented by a large body of literature (Fava et al., 1995). Eight of them refer to the concept of abnormal illness behavior: persistent somatization, functional somatic symptoms secondary to a psychiatric disorder, conversion symptoms, anniversary reaction, disease phobia, thanatophobia, health anxiety, and illness denial. The four syndromes of alexithymia, type A behavior, demoralization, and irritable mood are mostly related to the field of psychological factors affecting medical conditions.

Sirri and Fava (2013) discuss how the DCPR may contribute to both macroanalysis (the evaluation of functional relationships between different problems) and microanalysis (a detailed analysis of specific symptoms). As to macroanalysis, the DCPR expands the understanding of the relationships between psychosomatic and psychiatric diagnoses, such as illness denial and agoraphobia, and between different psychosomatic syndromes, such as irritable mood and type A behavior. At the level of microanalysis, the DCPR provides a better characterization of psychological distress, such as the identification of impairments in specific dimensions of well-being in demoralization. The inclusion of the DCPR in the clinical process may expand the spectrum of information about patients' functioning, leading to an increased accuracy in the decision-making phase.

Treatments

The fundamentals of treatment for patients with psychosomatic conditions were quite well described by Schwab (1979), which

1. provide the best medical care available with the help of laboratory investigative procedures wherever necessary,

2. prescribe medications according to a rational plan both for the physical as well as psychiatric components of the disorders,
3. work psychotherapeutically with the patient and preferably one doctor should have the basic responsibility for the patient, and
4. marshal social support systems for the patients.

Pharmacological Treatment

This is usually two pronged. Pharmacological agents appropriate for the physical or medical problem are necessary. Psychotropic agents like antidepressants are advocated as and when necessary. Usually, the severity of psychological or emotional problems determines the use of psychopharmacological agents.

Psychotherapies

Individual psychotherapy has an important role in alleviating psychological or emotional stressors. Many psychosomatic patients do not express their feelings verbally and many are probably alexithymic. Psychotherapy in such patients may not have much role, but in most other patients supportive psychotherapeutic efforts may prove to be beneficial.

Behavior Therapy

Behavior therapy appears to be a useful approach to certain types of problems. The emphasis is on how the patient acts and reacts in everyday life, and modifying behaviors associated with psychosomatic symptoms. Biofeedback has been demonstrated to be useful in certain psychosomatic disorders as migraine, hypertension, certain cardiac arrhythmias, and tension headache.

Usually, the approach to treatment has to be multidisciplinary, with the involvement for different professionals for complete management of psychosomatic disorders. Principles of yoga can be incorporated and tried systematically in the management of such disorders. Tinetti and Fried (2004) suggested that the aim of treatment should be the attainment of individual goals and the identification of all modifiable biological and nonbiological factors according to the biopsychosocial model constructed by Engel (vide supra).

The traditional medical specialties appear to be inadequate in dealing with functional symptoms and problems, which cut across organ systems. A holistic approach is needed with interdisciplinary involvement. There is a need to include functioning in daily life, productivity, performance of social roles, intellectual capacity, emotional stability and well-being, as an important part of clinical investigation and patient care. These aspects have become particularly important in chronic diseases, where cure cannot take place, and also extend over family caregivers of chronically ill patients and health providers. Patients have become increasingly aware of these issues. Psychosomatic interventions may respond to these emerging needs within the established medical system and may play an important role in supporting the healing process (Fava et al., 2012).

Conclusions

Psychosomatic medicine may be considered as a comprehensive, interdisciplinary framework for the assessment of psychosocial factors affecting individual vulnerability, course and outcome of medical diseases; holistic consideration of patient care; integration of psychological therapies in the prevention, treatment, and rehabilitation of medical conditions. Its primary goal is its incorporation into clinical practice. The interdisciplinary dimension that includes the psychosocial domain characterizes many rehabilitation units and pain clinics and is an operational translation of psychosomatic models (Fava and Sonino, 2009). The present challenge of psychosomatic research is to demonstrate its usefulness with stringent research methodologies. However, irrespective of the results of such research, and whatever name is given to the phenomenon, the care of medical disorders will stay to be a combination of pharmacological and psychosocial. In due course of time, spiritual factors would also gain more importance than at present, into the holistic care theme, and lead to research and care of bio-psycho-socio-spiritual medicine.

Psychotherapy and Hermeneutics

Abstract

The postmodern approaches in psychology (psychological constructivism, social constructionism, symbolic interactionism, narrative psychology) share the attempt at overcoming the Cartesian subject–object dualism and affirming the view of people as meaning-generating beings. For this reason, they take advantage of a dialogue with the philosophical tradition of hermeneutic phenomenology, concerned with the problem of interpretation and understanding of human experience. This article briefly reviews the similarities between hermeneutic phenomenology and the postmodern movement in psychology, before critically outlining the variegated field of hermeneutic approaches to psychotherapy.

The field of human sciences in recent years is showing an unusual kind of dialogue. Some biologists, cyberneticians, computer scientists, cognitive scientists, psychologists, and psychotherapists converse with each other, and – more surprisingly – they all converse with philosophers, in particular with phenomenologists and hermeneutic phenomenologists. What makes such a dialogue possible is an increasingly widespread dissatisfaction with the dominant view of psychology as a natural science, and the search for an alternative answer to the question 'what it is to know.'

A strong impulse to this trend has come from the spreading of broadly speaking 'postmodern' approaches in psychology, particularly in the form of social constructionism and psychological constructivism.

The movement of social constructionism (Gergen, 1985) is characterized by the recognition of the role played by language in the discourse about the world viewed as an artifact of communal interchange – following Berger and Luckmann's (1963) seminal volume *The Social Construction of Reality* – and acknowledges its roots in various phenomenologists who adopted an 'endogenic perspective' about the origins of knowledge.

Psychological constructivism developed from Ernst von Glasersfeld's (1984) interpretation of Piaget's view of knowledge in terms of a radical constructivist epistemology, according to which knowledge has to be meant as a construction of possible realities rather than as a representation of a world out there. Psychological constructivism too, has many commonalities with phenomenology and hermeneutics, as well as with the biological theory of knowledge developed by Maturana and Varela (1987), in its turn associated with Heideggerian hermeneutics (Winograd and Flores, 1986).

Close relationship with the above perspectives also have symbolic interactionism derived from American pragmatism, particularly from the work of George H. Mead (1934) on the emergence of mind and self from the social process of communication, which constitutes human experience, and the narrative approaches in psychology and psychotherapy fostered by Jerome Bruner's (1990) argument for a narrative organization of personal experience.

Though differing from each other with respect to the different emphasis given to the biological, cultural, and social factors implied in the personal construction of experience, all the above approaches share the attempt at overcoming the Cartesian subject–object dualism as well as a view of people as meaning-generating beings. For such features, they take advantage of a dialogue with the philosophical tradition of hermeneutic phenomenology (Chiari and Nuzzo, 2010), concerned with the problem of interpretation and understanding of human experience.

Postmodernism, Phenomenology, and Hermeneutic Phenomenology

The similarities between phenomenology and the postmodern movement in psychology appear so close that some expressions of the latter can be regarded as the present attempt to recover Husserl's (1970/1936) project of a refoundation of science – more specifically psychology – without foundations, that is, on the basis of people's lived, personal experience of phenomena. The interest in the human subject as an independently acting and responsible being also connects phenomenology with existentialism, whose main exponents are considered Friedrich Nietzsche, Søren Kierkegaard, and Jean-Paul Sartre.

Following Wilhelm Dilthey's (1988/1923) criticism to the application of the naturalistic method to the 'sciences of the spirit' supported by a differentiation between causal explanation and understanding as ways of acquiring knowledge, Franz Brentano (1995/1874) identified the peculiar characteristic of psychic phenomena in their intentionality (aboutness), that is, in their being directed on an object.

One of Brentano's students, Edmund Husserl (1983/1913), is often referred to as the father of phenomenology. He proposed a new way of looking at objects by examining how people, in their being intentionally directed on them, actually constitute them. Husserl's focus was on trying to understand human experience as it is lived prereflectively, that is, before resorting to any categorization or conceptualization. The notion of objects as real is not excluded, but 'bracketed' by means of the method of phenomenological reduction, or *epoché*, consisting in questioning what appears to be obvious and taken for granted in order to uncover new meanings.

Like phenomenology, Martin Heidegger's (1962/1927) hermeneutic phenomenology is concerned with the human experience as it is lived. However, Heidegger extended Husserl's proposal by describing the primary mode of human experience as engaged activity rather than detached knowing, and emphasizing the dimensions of historicality and sociality. Being is always a 'being-in-the-world' (*Dasein*), and finds itself thrown into the world and its possibilities via a history and a tradition. Unlike Husserl, Heidegger held that preunderstanding – the meanings of a culture that are already present before we understand and become part of our historicality of background – is not something a person can put aside. In other words, all understanding is connected to a given set of forestructures that cannot be eliminated, but that can be accounted for in the interpretive process. Ultimately, there is an indissoluble unity between the person and the world, and understanding is a basic form of human existence in that it is not a way we know the world, but rather the way we are (Polkinghorne, 1983).

Based on the hermeneutic phenomenology initiated by Heidegger, Hans-Georg Gadamer (1989/1960) argued that interpretation of a text arises from the dialectical interaction between the horizon supplied by the text and the horizon given to it by the reader, the 'horizon' being the range of vision that includes everything that can be seen from a particular vantage point. In the same way, each person in understanding the world, himself/herself and other people, is continuously involved in a process of interpretation. This, in turn, is bound and embedded in history because understanding deploys the knower's 'effective history,' that is, his or her personal experience and cultural traditions, to assimilate new experiences. Effective history constitutes the 'prejudices' or 'preconceptions' brought to bear in understanding, and implies the historicality of any interpretation. Both Heidegger and Gadamer share the notion that language is the foundation of being.

The role of the body – meant as 'phenomenal body' rather than 'objective body' – was brought into the phenomenological inquiry by the French philosopher Maurice Merleau-Ponty (1962/1945). The phenomenal body, or body-subject, represents a permanent condition of experience in the form of embodied subjectivity. Another French hermeneutic philosopher, Paul Ricoeur (1984–1988/1983–1985), argued that the self is essentially embodied, and that personal identity, as a whole, is a narrative identity in that we make sense of our own identities by telling ourselves a story about our own life experiences. Therefore, identities are not fixed structures or substances; instead, they are fluid and, until the story is finished, subject to revision.

The assumed susceptibility to change of personal narrative structures or meaning systems through an open-ended dialectical process of interpretation justifies the application of hermeneutic-phenomenological speculations to the field of psychotherapy.

Hermeneutics and Psychotherapeutic Approaches

Even though hermeneutic phenomenology and psychotherapy are distinctly different disciplines with different origins and goals, they show striking commonalities. To begin with, both disciplines are based primarily on language. Besides, hermeneutic phenomenology aims to understand and interpret meanings as expressed in written texts or in lived experience, as well as psychotherapy is concerned with the understanding and interpretation of the life experiences of people as expressed in their narratives. Such a community of interests should point at a close connection between the two; but this is not exactly the case, at least until few decades ago. The reason for the missed marriage resides in the development of both psychology and psychotherapy as naturalistic disciplines within a scientific discourse dominated by positivism and rationalism, and the resulting spreading of behavioral, cognitive-behavioral, and cognitive therapies. The psychoanalytic approaches escaped long an epistemological affiliation due to their distinctive subject – the unconscious – but for this same reason they were deemed untestable and unscientific by mainstream psychology.

Before the appearance of the postmodern trend, the phenomenological and hermeneutic-phenomenological criticism to the Cartesian, naturalistic approach had an important even though minority place in the development of psychotherapy.

The variegated field of existential-phenomenological approaches to psychotherapy sees the psychiatrist and philosopher Karl Jaspers as the acknowledged founder. His *General Psychopathology* (1997/1913), mainly based upon the empathic understanding of the personal worldviews of the patients and the subsequent search for general principles transcending the individual case, represents an alternative to traditional psychiatry and its categorical diagnosis.

Whereas Jaspers' approach to mental disorders can be regarded as a method of investigation capable of leading to more accurate generalization and classification, Ludwig Binswanger's (1963) and Medard Boss's (1963) *daseinsanalysis*, Viktor E. Frankl's (1959/1946) *logotherapy*, and Eugène Minkowski's (1970) *structural-phenomenological method* are more specifically designed to produce therapeutic effects. Significantly, Minkowski is quoted on the first page of *The Divided Self*, the most famous book of Ronald Laing (1955), which gave fresh contributions to the existential-phenomenological approach in psychiatry. Existential psychotherapy too (May et al., 1958) is based on the direct application of Heidegger's philosophy to the understanding of psychopathology, and aims at favoring the acceptance of the normal existential anxieties that come from confronting life.

The passage from early existential-phenomenological approaches to more recent hermeneutic-phenomenological ones entails a more vague delimitation of the field. The application of the basic tenets of hermeneutic phenomenology to the psychotherapeutic practice shows two main characteristics: (1) It is not identifiable as a specific school with adequate inner cohesiveness, but as the integration of some hermeneutic principles into several, already formalized psychotherapies, in ways depending on the basic assumptions of each; (2) Partly as a consequence, if interpretation, understanding, meaning, intersubjectivity, and narrative are the fundamental tenets of contemporary hermeneutic speculation, their closeness to the original thought of hermeneutic phenomenologists can significantly vary.

It is the case of many psychoanalytic perspectives, particularly Schafer's and Spence's proposals, which are held to have

opened the hermeneutic and narrative turn in psychoanalysis. Roy Schafer (1980) and Donald Spence (1982), in the same period but separately, offered interpretive perspectives in psychoanalysis by coupling the narrative tradition with the Freudian model. People tell stories about themselves and others, and these lend them to various understandings, each of which can legitimately claim to be true. In making interpretation, the analyst retells over and over these stories, accentuating certain features and placing others in parentheses. The end product is a radically new, jointly authored work. However, both the approaches have been criticized for not having altogether relinquished a correspondence theory of truth (Moore, 1999; Sass and Woolfolk, 1988).

Another break with the Cartesian 'myth of the isolated mind' espoused by Freud comes from George E. Atwood and Robert D. Stolorow's (1984) proposal of an *intersubjective psychoanalysis*, to some extent connected with Heidegger's hermeneutics and Husserl's approach to empathy and intersubjectivity. The basic unities of analysis are structures of experience open to a dialogical exploration with the contribution of the therapist's experiential world, within a contextual psychology that recognizes the constitutive role of relatedness in the making of all experience. Even their approach, however, has been said not satisfactorily in-line with the tradition of thinking to which it purports to belong.

The perspective called *dialectical constructivism* suggested by Irwin Z. Hoffman (1998) attributes to both the patient and the analyst the responsibility for the coconstruction of reality in the analytic process in order to promote new experience. Hoffman considers the terms 'constructivist' and 'hermeneutic' as interchangeable, but neither accepts von Glasersfeld's radical constructivism regarded as a kind of solipsistic relativism nor seems to overcome the traditional subject–object dichotomy as hermeneutic phenomenology does.

Much more absorbed by philosophical hermeneutics is the approach developed by Donnel B. Stern (1997). His redefinition of unconscious in terms of *unformulated experience* draws heavily on Gadamer's view of interpretation as a dialogical process, but also on Merleau-Ponty's notion of creative language, and Sartre's understanding of self-deception as *mauvaise foi* (bad faith).

Apart from the psychoanalytic approaches, Gestalt therapy (Perls et al., 1951) is an established existential-experiential form of psychotherapy that emphasizes phenomenological method, dialogic process, personal choice, and responsibility, recognizing its principal influences in European phenomenology and existentialism.

Since the end of the 1980s the application of the hermeneutic theory began to spread to other psychotherapeutic approaches (Messer et al., 1988).

The blend with hermeneutic phenomenology proves itself particularly well matched and fertile with the postmodern perspectives applied to psychotherapy – namely, the psychological constructivist and the social constructionist ones – due to the similarities above described.

Particularly with regard to the theory of disease, both the hermeneutic and the constructivist/constructionist approaches share an antimedical stance. The symptoms of mental disturbance are not regarded as expressions of a physical disease, but, in generic terms, as expressions of the person's attempt at conserving an adaptation with the social environment: they reveal primarily ontological – that is, 'being'-related – issues. They are part of personal narratives that reflect ways of life, manners of living, even though they can imply suffering. In addition to their objection to physical methods of treatment, both phenomenology and constructivism/constructionism reject the rationalistic psychotherapies aimed at correcting false perceptions or beliefs. Actually, the view of knowledge that both share implies that there is no way to have access to an ultimate reality, but that there are only personal interpretations open to alternatives in meaning. Such interpretations cannot be 'correct' or 'wrong,' since they are not based upon external, objective laws or truths that have been universally ascertained. This results in the therapist's attitude of acceptance of the clients' views of the world and themselves, as well as in the effort of empathically understanding them, as a common basis for favoring a therapeutic process and relationship in ways that can differ according to the different theoretical approaches.

A Gadamerian hermeneutic learning is clearly and explicitly present in the social constructionist paradigm as applied to family therapy. According to Anderson and Goolishan (1992), human beings are language-generating and meaning-generating systems, and the therapeutic system itself is linguistic in nature. Starting from a 'not-knowing' position – an attitude expressing a need to know more about what has been said rather than convey preconceived opinions and expectations about the client, the problem, or what must be changed – the therapist becomes part of a linguistic system and a therapeutic conversation wherein the therapist and the family together explore the family's problem through dialogue, aimed at its dissolution and at increasing the potential for the narrative development of new agency and personal freedom.

The constructivist approach to psychotherapy derived by Kelly's (1955) personal construct theory, the forerunner of contemporary constructivist psychotherapies, is having in recent years a narrative hermeneutic development (Chiari and Nuzzo, 2010) through a comparison with Gadamer's hermeneutic conversation and Ricoeur's hermeneutics of narrative self and recognition. Even though Kelly explicitly rejected a comparison with phenomenology, his theory shows many commonalities with its basic tenets which recent analyses are revealing and emphasizing.

As the postmodernist-hermeneutic phenomenological approaches in psychotherapy began to counter the supremacy of the naturalistic-positivist ones, the research methods also showed a significant shift (Polkinghorne, 1983). Qualitative research, once confined to anthropological and sociological research – or, in psychotherapy, to the case studies of rare pioneers as Freud, Maslow, and Rogers – claimed its justification within a scientific inquiry dominated by quantitative research methods and statistical correlations, which had produced results with limited relevance to the analysis of the therapeutic process and relationship. In this case too, though qualitative research aimed at the interpretation of textual material, spoken narratives, therapeutic conversations or change processes are professed to be hermeneutic or interpretive, seldom obeys adequately the rules of philosophical hermeneutics. Anyway, it represents at least a third road of inquiry between the natural scientistic and the genuine

hermeneutic approach in the complex field of psychotherapy research.

Psychotherapy and Pharmacotherapy

Abstract

In the last 30 years, we have seen a rise and now prevalence of the combination of pharmacotherapy and psychotherapy for patients with a wide variety of psychiatric conditions. The treatment modality that is often used is a collaborative one, in which there is a therapist who provides the psychotherapy and a physician or other clinician, such as nurse practitioner, who provides the medication. There may be more than two clinicians involved, such as a family physician who oversees the care, a psychiatrist, and a psychologist or social worker who provides the psychotherapy. There are positive aspects and negative aspects for this split type of care. Certain group of patients might be at higher risk for difficulties with split treatment, such as those with cluster B types of personality disorders. This is an important area for research and education and improved methods of communication between the providers and the patients.

Combined psychopharmacology and psychotherapy is a common treatment form in modern psychiatric practice. Numerous research studies confirm that the combination of psychopharmacology and psychotherapy treatments are more effective than each alone. Such clinical care is often provided in collaborative treatment arrangements wherein a psychiatrist or other physician provides the medication and manages the medical issues while a nonphysician therapist provides the psychotherapy. In the last several years, the term 'integrated' care is sometimes used in place of the term 'collaborative' while in some health systems, the terms are not necessarily synonymous.

It should be noted that treatments with psychopharmacology and psychotherapy have become common for all psychiatric patients, reflecting the importance of biological psychiatry. Since the early 1990s, there has also been an expansion in specific types of psychotherapies with personality disorders, such as dialectical behavior therapy (Linehan et al., 1993), mentalization-based therapy based on dynamic therapy (Bateman and Fonagy, 1999, 2001), fueling the need for collaborative treatment.

There are positive and negative aspects of providing collaborative treatment and various associated ethical and legal dilemmas. Some of the positive aspects include better utilization of the special talents of both therapist and psychiatrist; cost-effective utilization of resources; and enhanced opportunity for patients to select clinicians with similar ethnic and/or gender background. Negative aspects include splitting of clinicians; potential problems in prescribing decisions due to inadequate knowledge of the content of psychotherapy; and clouded legal and clinical responsibilities. It is important that the clinicians and patients involved in such treatment understand and define their own roles and responsibilities, treatment objectives, and optimal ways of communicating patient care issues.

Background and Introduction

Combined psychopharmacology and psychotherapy is a treatment form quite accepted and ubiquitous in modern psychiatric practice (Beitman, 1983). It may have its origins in the writings of Fromm-Reichman wherein the role and responsibilities of the analytic treating therapist were differentiated from the managerial therapist, a feature of long-term psychotherapy in the 1940s (Fromm-Reichman, 1947). Further explicated by Firman, the rationale of this division of labor was based on analytic principles: the 'psychotherapist' should ideally not be in any managerial relationship with respect to the patient so that the patient's fantasies about the therapist could be viewed and analyzed as material emanating from the patient's own self (Firman, 1982). According to Firman, the usefulness of this relationship is twofold: the 'outsider' (managerial) therapist can serve as a negative split object upon whom the patient can focus her own negative features. This serves to allow the tenuous whole-object relationship with the treatment therapist to proceed without jeopardy. Firman viewed the splitting that would occur in such collaborative relationships to be in a therapeutic setting and thus under better and safer control for the patient (Balon, 1999; Firman, 1982).

Since then, the techniques used in analytic practice and with patients in long-term psychotherapy have been transferred to almost all types of psychotherapy. Fueling this have been newer and simpler types of psychotropic medication which physicians, other than psychiatrists, feel comfortable prescribing (Horgan, 1985; Regier et al., 1978; Schurman et al., 1985) and systems of care, which have advocated for lower costs for patient care. Additionally, numerous research studies confirm that the combination of psychopharmacology and psychotherapy treatments are more effective than each alone (Goldsmith et al., 1999; Karasu, 1992; Koenigsberg, 1994; Manning et al., 1992) adding incentives for therapists to seek consultation for their patients from physicians regarding medication.

In modern psychiatry, collaborative treatment wherein a psychiatrist or other physician provides the medication and manages medical issues while a nonphysician therapist provides the psychotherapy is a common and growing treatment modality. While the field has not definitively defined this paradigm, the American Psychiatric Association published guidelines describing the responsibilities in

a collaborative relationship, noting that the psychiatrist and therapist share responsibility for the care of the patient in accordance with the qualifications and limitations of each person's discipline and abilities (American Psychiatric Association, 1980). Various terms have been used in the literature and in clinical care to describe this practice, which include medication backup, split treatment, combined treatment, medical management, cotreatment, triangular treatment, collaborative treatment, medical backup, and parallel treatment. For the purposes of this section, we will call this practice 'collaborative treatment.'

What has not been definitively researched, however, are the best methods for providing collaborative treatment. Recognizing the cognitive and emotional problems for all parties, Goldsmith and coworkers and others have sought to better explicate the potential difficulties and sources of conflict (Berg, 1986; Bradley, 1990; Chiles et al., 1984; Goldsmith et al., 1999; Kingsbury, 1987). Others have described the positive aspects of this form of treatment (Balon, 1999; Michels, 1995).

The remainder of this article will focus on some of the highlights of collaborative treatment: the positive and negative aspects, legal and ethical issues, and suggestions for maximizing the collaborative process.

Positive and Negative Aspects of Collaborative Treatment

The combination of psychopharmacology and psychotherapy, or collaborative treatment, has some positive and negative aspects. As noted by Beitman (1983), collaborative treatment is based on a triangular relationship between psychiatrists, patients, and nonmedical therapists. In an ideal world, such a triangle should have just positive aspects, e.g., utilization of special talents. Triangular relationships, however, could also be a breeding ground for difficulties or negative aspects, such as splitting. The negative aspects of collaborative treatment do not arise only from patients' pathology. As Brill (1977) pointed out, "More and more nonmedical mental health professionals began to resist and resent working under the direction of a psychiatrist. They believe that their own professions and therapeutic skills have advanced to the point that independence and self-determination were justified." He emphasized the emergence of territorial conflicts arising in collaborative 'team' treatment. The territorial or turf conflicts and concerns are a bilateral issue – psychiatrists, as much as nonmedical therapists, frequently view the 'other side' as a competitor rather than a collaborator.

Collaborative treatment could benefit the patient only if it is truly collaborative, when positive aspects are maximized and negative aspects minimized. Awareness of the possible positive and negative aspects of collaborative treatment is the first step in maximizing the collaborative relationship (see below).

Positive Aspects of Collaborative Treatment

Utilization of Special Talents of Both Therapist and Psychiatrists

As Balon (1999) pointed out, both professionals may possess expertise in special areas, e.g., mood disorders, eating disorders. Firman (1982) also pointed out that a psychiatrist who is a skillful psychotherapist could also serve as a second therapist, or a negative split object, on whom the patient focuses many of his/her own disowned negative features.

Cost-Effective Utilization of All Resources

This is an issue especially important to patients. Due to various economic pressures, most patients cannot afford psychotherapy by psychiatrists unless they have good mental health care benefits. In many cases, insurance companies either do not cover psychotherapy by psychiatrists or pay an amount that is not acceptable by psychiatrists. Psychotherapy provided by nonmedical psychotherapists is considered cheaper (a contentious issue; see Goldman et al., 1998) and frequently is covered by insurance companies. Most patients thus can still benefit from the combination of pharmacotherapy and psychotherapy.

It is important to note there are managed care companies, which are reluctant to approve treatment sessions with seriously ill patients who are not receiving medication; this tenet is another factor in the use of the collaborative care model.

Better Opportunity for Patient to Select Therapist with Similar Ethnic and/or Gender Background

Some authors (e.g., Foulks and Pena, 1995) have advocated that matching a patient with a therapist or physician of a similar ethnic or cultural background may facilitate the process of psychotherapy or pharmacotherapy. Others (Yamamoto et al., 1993) have warned that this matching could have its pitfalls and could be discriminatory at times. Nadelson and Zimmerman (1993) have recommended that a patient's request for a therapist or psychiatrist of a specific gender, ethnicity, or race, or a patient's uneasiness with a particular therapist's or psychiatrist's gender, ethnicity, or race should be an issue explored and addressed in therapy.

Increased Time and Resources Available for Patients

The combination of a 20-min medication review and 50-min therapy session represent more resources than just one of these modalities and is an unquestionable benefit. The combination of resources is also advantageous during the temporary absence of a psychiatrist or therapist.

Increased Amount of Clinical Information

There may be information that the patient feels more comfortable sharing with their therapist and vice versa. Thus, psychiatrist and therapist should set time aside to share information, impressions, and concerns and to support each other in their efforts to help patients (Pilette, 1988).

Enhancement of Adherence

As Paykel (1995) pointed out, psychotherapy may assist or possibly hinder medication compliance. Similarly, collaborative treatment may also increase compliance with psychotherapy. To date, the difference in adherence between collaborative and split treatment has not been delineated, although collaborative care seems to improve adherence. Levine Baruch (2012) has studied the patient's sense of satisfaction and subsequent adherence in split treatment is

complex and multifactorial depending on the matching of the treatment with the patients' treatment preferences, prioritized needs, and relational style, the patient may exhibit varying levels of satisfaction and adherence behaviors (Levine Baruch, 2012). Much of the studies to date have focused on adherence to medication, not to psychotherapy, in collaborative versus split treatment.

Professional and Emotional Support for Both Therapist and Psychiatrist

As Pilette (1988) pointed out, such support is especially important when the patient is difficult to treat and also during times of crisis. When there is collaboration with a primary care physician, the mental health professional can confer with someone who may have a long-standing relationship with and understanding of the patient, which may enhance adherence.

Negative Aspects of Collaborative Treatment

Inappropriate Prescribing Decisions without Knowledge of the Content of Therapy

The prescribing psychiatrist may not always be aware of all the inner conflicts or external pressures felt by the patient. For instance, the psychiatrist may prescribe medication for anxiety that arose after an important intrapsychic conflict was addressed in therapy with the nonmedical therapist.

Potentially Discrepant Information Given by the Patient to Each Clinician

Frequently, the discrepant information provided by the patient to both treating professionals could lead to decisions with serious consequences. This issue is directly related to the next one – splitting.

Splitting of Clinicians

This is probably the most frequently discussed negative aspect of collaborative treatment. Treatment provided by two persons provides a fertile ground for a patient to develop negative transference, to introduce problematic countertransference, and to split the prescribing psychiatrist and therapist. Splitting may lead to noncompliance with any of the treatments.

Patients with personality disorders, in particular Cluster B traits with emotional liability, depressivity, separation insecurity and hostility, may 'split' even without a 'split' treatment relationship so this problem must be acknowledged when a patient is treated in a collaborative care model (Schlesinger and Silk, 2009). Patients may idealize or devalue one or the other clinician making the roles of 'good' and 'bad' treater shift. The treaters may unconsciously identify with the projected characteristics promoted by the patient and may respond accordingly (Schlesinger and Silk, 2009; Gabbard, 1989; Gabbard and Wilkinson, 1994).

Unclear Confidentiality

As Pilette (1988) pointed out, is the collaborative treatment an occasion for free communication between a therapist and psychiatrist without the patient's consent? What if the patient asks that some important information not be related to the other treating professional? These issues are complicated and need to be discussed and resolved.

Clouded Legal and Clinical Responsibility

It is not always clear who is legally responsible for various aspects of collaborative treatment. It is rather safe to assume, however, that the psychiatrist will most likely be found legally responsible for all aspects of clinical care including inappropriate or negligent supervision (Balon, 1999).

Lack of Reimbursement for Collaboration

The fact that third party payers do not reimburse for collaboration somewhat hinders the collaborative treatment.

Various Misconceptions of Patient, Therapist, and Psychiatrist

These include issues such as therapists and psychiatrists ignoring the psychological meaning of medication, psychiatrists' belief that therapists should always agree with and support physicians' decisions, and patients' common perception that psychiatrists are only interested in prescribing medication (Goldsmith et al., 1999).

This is only a brief summary of positive and negative aspects of collaborative treatment. More thorough discussion of both positive and negative aspects is provided in the two introductory chapters of *Psychopharmacology and Psychotherapy. A Collaborative Approach* (Goldsmith et al., 1999; Riba and Balon, 1999).

Legal and Ethical Issues

Legal

The major worry in collaborative treatment is that with two clinicians delivering the care, there will be a loss of information or understanding of what may be occurring for the patient. There are currently no standards in place for how frequently or for how long patients should be seen by physicians if collaborative treatment is provided. There is, therefore, a broad range of frequency of visits and communication patterns between the patient, therapist, and physician, which range from ideal to inadequate. Because medications are involved in collaborative treatment and historically have been the source of significant legal exposure, the issue of medical practice is an important topic for discussion. Negligence underlying malpractice liability is of two types: (1) carelessness in gathering necessary data about a patient and (2) negligence in assessing that information in determining appropriate treatment modalities, interventions, providing precautions, etc. (MacBeth, 1999). Psychiatric medications, like all medications, are associated with side effects. Physicians who prescribe medications become liable, if there is a deviation in the accepted uses of the medications and there results harm to the patient. It is critical for physicians to obtain informed consent from patients when prescribing medication and also to ascertain liability for patient suicide.

If patients are going to be seen infrequently by the prescribing physician, there must be a way for the physician to set up a communication pattern where side effects and sociality are made known, to the extent possible, to the physician, on a regular basis. For example, if a patient were being seen by the physician every 6 months but the therapist is seeing the patient weekly, and then the therapist and physician must discuss how issues and developments about the patient can be communicated.

In collaborative treatment, it must be determined how the treatment plan is shared between the clinicians; how emergencies including hospitalization will be managed; and who is directing the psychotherapy. The setting may play a large role in the extent to which the physician, therapist, and patient communicate. In many public settings, for example, the psychiatrist only sees the patient infrequently. The patient, however, has a case manager whose job it is to communicate to the various clinicians about the patient. In managed care settings, psychiatrists may find themselves in relationships with therapists whom they do not know and who are unaware of their skills, talents, experience, etc. There may be disincentives for the physician to see the patient often, even when more psychosocial problems accumulate for the patient. In collaborative treatment in certain settings, patients sometimes do not even know who the doctor is and often the physician has not had the chance or taken the opportunity to meet with the patient's family, since others (therapists, case managers, nurses, and a previous physician) might have already done so.

There is, therefore, a range of potential legal problems for physicians who engage in collaborative treatment. Physicians are usually viewed as 'the deep pocket' when there is a lawsuit regarding a patient's treatment. The physician usually carries more insurance than the nonphysician therapist and is viewed by juries as 'being in charge' by virtue of education and experience. Even if the plaintiff's attorney does not believe that the psychiatrist was central to the matter, it is often likely that the psychiatrist will be part of the suit to extend the limits of insurance and to try to reach 'the deep pocket.' There is also the problem that occurs when there is more than one defendant. One defendant can try to make their case stronger by blaming the other defendant, thereby turning against one another. Another problem is that even if medications or the medical management provided by the physician is of minor importance to the reason for the suit, regardless of the realities, the physician is often viewed as being in charge while the therapist is viewed as subordinate to the physician.

Finally, physicians are increasingly signing contracts to provide services for patients in managed care. These contracts are usually written by the companies themselves and the fine print is not read carefully by the physician, causing them to be implicitly involved in relationships with therapists that are not collaborative in nature but more supervisory. This practice, therefore, often puts the physician at further risk.

There are some suggestions for clinicians to heed in order to decrease legal risk in collaborative treatment:

1. Clinicians should understand the settings they are practicing in, including its operations and routines.
2. Care should not be compromised because of the setting or because the patient is being treated in a collaborative model.
3. Use good communication techniques with professionals with whom you are sharing responsibility for the patient. Document these discussions.
4. If supervision is part of the collaborative relationship, then set regular supervision times and amend depending on the patient's condition and needs.
5. Read the fine print in all managed care and other contracts that are signed.
6. For a more thorough discussion of these issues, please see the work of MacBeth (1999).

Ethical

When patients receive collaborative treatment because that is what is deemed best for their care, then there is not an ethical problem. An ethical and clinical dilemma, however, may exist if such care is provided because of cost considerations (Lazarus, 1999). While some patients clearly benefit from team approaches to care, others do not. Research is starting to help us discriminate between such patients and determine mental health outcomes in different practice and fee arrangements (Rogers et al., 1993; Wells et al., 1992). Goldman et al. (1998), for example, has shown that for many patients, psychotherapy and psychopharmacology provided by a psychiatrist alone is as effective as and less costly than collaborative treatment.

There are four bioethical principles that need to be considered when one is providing collaborative treatment (Beauchamp and Childress, 1994):

1. Beneficence: the covenant between professional and patient to do what is in the patient's best interest;
2. Nonmaleficence: the principle of doing no harm;
3. Autonomy: respect for the individual rights of patients, especially in the area of informed consent and treatment refusal; and
4. Justice: the fair treatment of patients.

As noted by Lazarus, when determining ethical dilemmas related to collaborative treatment, any two or more of the above principles may be compromised or in conflict (Lazarus, 1999). In this era of cost containment and lack of standards regarding collaborative treatment, all of these principles are being tested. The American Psychiatric Association (APA, 1993) and the American Medical Association (AMA, 1994) have addressed ethical principles and have recognized the importance of collaborative treatment. Section Conclusion of the AMA principles states: "A physician shall continue to study, apply and advance scientific knowledge, make relevant information available to patients, colleagues, and the public, obtain consultation, and use the talents of other health professionals when indicated" (AMA, 1994).

It is a complex area where psychiatrists and other mental health professionals engaged in collaborative treatment can find themselves in ethical dilemmas. Some of this has to do with the settings and the rules within those settings; physician–therapist relationships that should be modified because of the patient's condition but may not be; need for differential types of supervision and monitoring between therapist and physician but which are not taken into consideration; fee schedules that cause disincentives for providers to see patients more often, even when needed; lack of understanding by the patient of the nature of the collaborative relationship between the providers, etc.

In order for health professionals to provide psychotherapy and psychopharmacology in an ethical manner, Lazarus (1999) suggests:

1. The physician and therapist keep themselves adequately and appropriately informed of the nature of the treatment and the progress of those patients cared for in this type of treatment.
2. The physician and therapist assure themselves that the treatment is being carried out competently and adequately.
3. The physician and therapist provide enough supervision, consultation, or collaboration to ensure that their ethical, medical, and legal responsibilities toward the patient are satisfied.
4. The collaborative treatment is consistent with any local, state, or national guidelines outlining psychiatrists' responsibilities to patients and in conformity with licensure requirements and the scope of practice of all the health care professionals involved.

Maximizing the Collaborative Relationship

Providing combined psychopharmacology and psychotherapy is a complex enterprise, much more difficult than a single therapist providing either the psychotherapy, psychotherapy and pharmacotherapy, or pharmacotherapy. There are, therefore, some general suggestions offered that might be useful.

It is incumbent upon the clinicians and patients involved in such treatment to be aware of the complicated nature of this form of care. While combining psychopharmacology and psychotherapy offers distinct and unique advantages, there are problems, as noted in the above section. Time and attention must, therefore, be given to the process of treatment as well as the content. Written contracts between clinicians have even been suggested as a way to delineate the specific duties and responsibilities of providers (Appelbaum, 1991). Other authors have suggested that the patient be part of the three way contract and so be asked to sign such agreements for care (Chiles et al., 1984; Woodward et al., 1993). Specific guidelines for combined care based on the phases of treatment (initial, mid, termination) have been described by Rand (1999). Kahn (1990) has delineated the ideological differences that the psychotherapist and psychopharmacologist often have, and the identified roles they must play in order to provide such treatment.

It is probably prudent for clinicians, both physicians and nonphysician therapists, to review their case mix from time to time. Goals would be to limit the numbers of such collaborative treatments based on the amount of time it takes to speak with other therapists, review and develop joint treatment plans, read other clinicians' notes, determine the background and treatment orientation of the clinicians who are collaborating on patient care, work with patients' families and significant others, develop vacation and coverage schedules with collaborating clinicians, discuss such arrangements with patients, etc. Such thoughtful processes may lead to a decrease in malpractice exposure and ultimately more efficient and useful clinical care.

Attention must be paid carefully to the issue of confidentiality and communication between clinicians and with the patient. Consent to discuss treatment plans as well as content of sessions must be clarified. Since it is impossible to initially predict what will be important or relevant, the patient must be cognizant of these communication patterns and provide consent to clinicians at the beginning of treatment. Any barriers to such communication should be discussed with the patient as well as any relevant family members. It should be determined how the information will be transmitted, that is by telephone, electronic communication, mail, in person, etc., and how often. Communication must be regular, not just when there is a crisis (Vasile and Gutheil, 1979). It is critical that the patient understands which type of problems should be discussed with which clinician. Further, patients should not be placed in the position of needing to relay information between clinician and the other.

Even with that said, it will sometimes be difficult to sort out. As an example, often what seems like uncomfortable medication side effects could be resistance to taking medications. What seems like a dynamic issue in therapy could in fact be a medical problem. Clinicians need to be supportive of the treatment plan; listen for resistances to either psychotherapy or pharmacotherapy; try to delineate the boundary of the treatment being provided by the individual clinician; and talk regularly with one another about the patient's progress. Because of financial remuneration patterns and modern contractual agreements between clinicians and payers, it is easier than ever for a clinician to find themselves responsible for large numbers of patients, many of whom are not being seen frequently or regularly. This can lead to problems with the inherent doctor–patient relationship that is the hallmark of providing care, whether it is pharmacotherapy, psychotherapy, or both. The clinician is well advised to review the ethical boundaries of the work situation and the nature of the tasks required.

Certain patient populations may be at higher risk in such combined therapies. For example, patients with personality disorders are notoriously difficult to treat given their problems with interpersonal relationships. As summarized by Silk (1999) and others, patients with Cluster B diagnoses are prone to splitting (Kernberg, 1975); often do not tell the entire story equally to all clinicians (Main, 1957), and tend to externalize problems (Silk et al., 1995). When there is concomitant substance abuse, emotional liability, and self-mutilating behaviors, combined treatment with more than one clinician can be enormously difficult and complex.

Finally, psychiatry residency training programs and graduate programs in social work and psychology must develop education and training in the specific area of combined treatment. Teaching psychopharmacology alone or psychotherapy without integrated pharmacotherapy is no longer sufficient. There needs to be curricula developed and teachers who are trained themselves in how to deliver such care with emphasis on learning to communicate clearly with other professionals; thinking clearly about diagnosis and treatment strategies; and developing leadership abilities (Spitz et al., 1999).

Conclusion

Providing combined pharmacotherapy and psychotherapy is a growing and important part of psychiatric care. It is a complex dynamic treatment, fraught with potential pitfalls but offering many advantages. Importantly, it offers a unique opportunity for a bio-psychosocial and fiscal model of care and interesting areas for future research and clinical development.

Abstract

Psychotherapy has its origins in two healing traditions – the magico-religious and the medico-scientific. It was with the publication of *Studies in Hysteria*, by Josef Breuer and Sigmund Freud, and their concept of 'free-association' – the patient was instructed to disclose whatever came into their mind while the therapist adopted an attitude of 'evenly-suspended attention' in listening to and interpreting the material – that the latter was firmly launched. Freud revised his theories at numerous points and many of his colleagues extended the boundaries of psychoanalytic thinking. But differences of opinion soon surfaced, which led notable figures to evolve their own 'schools'. Jung and Adler were two foremost dissidents in Europe, Horney, Fromm, and Sullivan in the US, and Klein in Britain. Humanistically oriented schools became popular in the 1960s and 1970s, mainly in the US. Among their chief features were challenging patients with the way they avoid emotionally significant matters in the 'here-and-now'. Feminist-based psychotherapies evolved in the 1980s, reflecting a range of opinion from condemning Freud as a misogynist to appreciating his linkage of life experience, innate drives, and defenses in influencing vulnerability. The second half of the twentieth century saw the evolution of treatments conducted with more than one person: groups of strangers and families.

Although the therapy of stranger groups was experimented on early in the twentieth century, it was not until World War II that major developments ensued. In the US, the move to the study of group process was spearheaded by social psychologists. Paralleling the human potential movement in the 1960s, the group movement transferred its focus from group to personal dynamics, and spawned the encounter movement. Formal group therapy under professional leadership then assumed a more prominent role. Yalom pioneered the study of therapeutic factors specific to the group rather than transposing psychoanalytic or other theories from the individual setting. Alongside this interest in group therapy came the idea of working with the family. Many competing theories of how families become dysfunctional resulted, but principles of Systems Theory dominated. Therapists also began to consider that families might be stymied by their interpretation of past experience. With the narrative a family conveys about their lives regarded as a construction which organizes experience in particular ways, other narratives are excluded. Systematic research in the psychotherapies was a low priority for decades. An impetus was Eysenck's critique of treatment as ineffective. Since then research has yielded much knowledge about whether psychotherapy works and how it works.

Several reviews, including sophisticated methods such as meta-analysis, point to psychotherapy benefiting suitably selected patients. Research on comparative effectiveness has shown a consistent pattern – that 'everyone has won and must have prizes,' a finding probably attributable to factors common to all approaches. Attention has also been devoted to the therapeutic process, which has been shown to be as salient as that on outcome since only with the study of what occurs in treatment can therapists appreciate factors accounting for improvement.

Psychotherapy – the systematic application of psychological principles to accomplish symptomatic or more substantial personality change – has its origins in two healing traditions – the magico-religious and the medico-scientific (Bromberg, 1959). The idea that human experience is influenced by supernatural forces and that certain people have the power to intercede with these forces dates back to antiquity. Shamans and sorcerers have resorted to amulets, magical potions, and incantations for centuries. They have also conducted exorcism and induced altered states of consciousness.

With the Age of Reason, interest was aroused in the newly discovered phenomena of electricity and magnetism. Anton Mesmer (1734–1815), a brash physician, drew on the latter when propounding his theory of animal magnetism. Since the body contained 'magnetic fluid,' and this could become disturbed, by applying magnets to various parts a patient could be relieved of pain and other ailments. While Mesmer's work was ultimately denounced by a Royal Commission and he was forgotten, the observation that his methods appeared to help patients continued to attract attention. James Braid (1795–1860), a Manchester doctor, noted that he could induce a similar trance-like state by getting people to fix their gaze on a luminous object. Labeling the phenomenon hypnotism, he proceeded to demonstrate its effectiveness in treating a range of conditions.

The doyen of French neurology, Jean Martin Charcot (1835–93), considered hypnosis a neurophysiological process, and set about its study in states like somnambulism and hysteria. His pupil Pierre Janet (1859–1947) suggested that the latter was brought about by weakening of a higher brain function, resulting in a constriction of consciousness. In this 'dissociated' state thoughts could not be integrated, and symptoms were beyond the reach of consciousness.

In an alternative explanation, Ambroise Liebeault (1823–1904), and Hippolyte Bernheim (1840–1919) in France posited a narrowing of attention in hypnosis which rendered the patient vulnerable to the therapist's influence by suggestion. Far from invalidating hypnosis, the power of suggestion could be investigated scientifically and accepted as a bona fide therapy.

Freud (1856–1939) had studied briefly with Charcot in 1885–86 and became enthusiastic about new possible treatments for hysteria. Freud's mentor, a respected Viennese physician, Josef Breuer (1842–1925), had described the treatment of a young woman who suffered from an array of marked hysterical symptoms. Instead of suggesting disappearance of

the symptoms, Breuer had encouraged Anna O (the pseudonym given to her) to talk freely about her life under hypnosis. She did so and over time began to share memories about her father's illness. Breuer noted that after each session, his patient became less distressed and her symptoms improved. Anna herself referred to this approach as her 'talking cure' or 'chimney sweeping'; Breuer termed it 'catharsis'. Whereas Charcot had described physically traumatic events as possibly causal, in his hysterical patients, Breuer and Freud's interest focused on psychological trauma such as humiliation and loss. Freud also became less keen on applying hypnosis.

Their volume, *Studies in Hysteria*, which included the case of Anna O., and four others treated by Freud himself, also contained ideas on defense mechanisms and an account of various techniques including suggestion, hypnosis, and catharsis. Most importantly, however, was the new concept of 'free-association': the patient was instructed to disclose whatever came into their mind, without any censoring, while the analyst adopted an attitude of 'evenly-suspended attention' in listening to and interpreting the material.

On the basis of his subsequent self-analysis and further clinical experience, Freud elaborated his theory of infantile sexuality. Sexual fantasies in young children centered around the triangular relationships of love and rivalry with their parents (the Oedipal complex). Promoting free association of this theme, as well as of dreams, slips of the tongue, and other unconsciously-based thoughts, feelings, and fantasies, Freud emphasized the centrality of the complex in the neuroses. While catharsis and insight (making the unconscious conscious) seemed pivotal to therapy, Freud soon realized that other factors also operated, particularly the role of transference, i.e., how feelings, thoughts, and fantasies stemming from childhood experiences and revived in current relationships are 'transferred' onto the analyst.

Interpretations were directed at this threefold nature of the analytic experience. The therapist's response to transference (countertransference) led to analysts having their own personal therapy, the aim being to minimize it, and thus to be thoroughly objective in attending to the patient's disclosures (Ellenberger, 1970).

In summary then, psychoanalytic psychotherapy elaborated the following processes: the patient's unbridled disclosure of whatever enters his or her mind – free association; the transference of infantile and childlike feelings and attitudes to the therapist which were previously directed to key figures in the patient's earlier life; interpretation of the transference as well as of defenses the patient applies to protect him/herself and the resistance he/she manifests to self-exploration; and finally, the repeated working through of the discoveries made in treatment. The ultimate aim is insight with translation into corresponding change in behavior and personality.

Variations on a Theme

Freud revised his theories at numerous points in his long professional life. In addition, many colleagues extended the boundaries of psychoanalytic thinking. But differences of opinion soon surfaced, some radical. The nature of psychoanalysis then, especially Freud's intolerance of dissent, led notable figures to leave the fold and to evolve their own models on which corresponding schools of therapy were established. Jung and Adler were two foremost European dissidents; Karen Horney, Erich Fromm, and H.S. Sullivan were pioneering neo-Freudians in the US; and W.D. Winnicott and Melanie Klein were prominent in Britain (Mitchell and Black, 1995).

Carl Gustav Jung is perhaps the most critical dissenter since he was clearly being groomed to take over leadership of the psychoanalytic movement. But he was also celebrated because of his own contribution. Specifically with regard to psychotherapy, he advanced the notion of 'individuation' – the aim was to discover all parts of oneself and one's creative potential. Jung was less concerned than Freud with the biological roots of behavior, especially infantile sexual development, but rather emphasized social and cultural factors. The role of transference was replaced by a more adult type of collaboration.

Furthermore, the unconscious for Jung is not merely the repository of the individual's history but also a wider social history, a phenomenon Jung labeled the collective unconscious. He arrived at this notion through a study of myths, legends, and symbols in different cultures, in different epochs. That these are shared by a variety of cultures is not fortuitous but reflects cosmic mythical themes or archetypes, a salient feature of man's collective history.

Alfred Adler (1870–1937), a Viennese physician, was like Jung a prominent dissenter. Adler joined Freud's circle in 1902 but broke away to form his own school of 'individual psychology' after 9 years. An important tenet concerns individual development. We begin life in a state of inferiority, weak, and defenseless, for which we compensate by striving for power and by evolving a lifestyle to make our lives purposeful. The pattern that emerges varies and may include such goals as acquisition of money, procreation, high ambition, or creativity. The drive for power and choice of lifestyle may, however, go awry in which case a neurosis results. A path is followed which leads to ineffective efforts to cope with the feeling of inferiority and assumption of a facade or false self.

Adler regarded therapy as a re-educative process in which the therapist, who serves as model and source of encouragement, engages in a warm relationship with the patient and enables him or her to understand the lifestyle he/she has assumed. Unconscious determinants of behavior are less crucial than conscious ones and the term 'unconscious' is used only descriptively to refer to aspects of the person that are not understood by him.

Freud's insistence on innate drives and infantile sexuality not only led to the schisms with Jung and Adler but also spurred a new generation of analytically oriented analysts to concentrate on interpersonal aspects of psychological experience. In the US, Sullivan pioneered the school of 'interpersonal psychiatry,' in which the therapist adopted the role of participant observer in treatment, the transference providing one opportunity to explore communication and its breakdown in the patient's interpersonal world.

We can consider the chief features in the approach of the neo-Freudians by looking briefly at Karen Horney (1885–1952). She became disenchanted with Freud's rigid focus on instinctual biological factors, arguing that cultural factors were more salient, as reflected in the differences in psychological development and behavior among different

sociocultural groups. Indeed, behavior regarded as normal in one culture could be viewed as neurotic in another.

In line with her emphasis on culture, Horney advanced the role of parental love in the life of a young child. Children typically suffer anxiety, a consequence of feeling helpless in a threatening world. The child reared in a loving atmosphere succeeds in overcoming basic anxiety. By contrast, the deprived child comes to view the world as cruel and hazardous. An inevitable result is low self-esteem.

The task of therapy is to examine the patient's defective patterns in relating to others. In part this is achieved through study of what transpires between patient and therapist. But there is no emphasis on transference as occurs in Freudian analysis. Therapy aims to enable the patient to move *with* others, by engaging in relationships which are reciprocal and mutual. Another goal is greater self-realization, with freedom from determined modes of thought and action.

While the neo-Freudians were establishing a new pathway for psychoanalysis, a group was equally innovative in the UK and France. In the UK, Melanie Klein (1882–1960), a physician hailing from Berlin, concluded from her study of children's play that the Oedipal complex, as described by Freud, was a late expression of primitive unconscious anxieties which children experienced in the first 18 months of life. Given that these states could be reactivated in adult life, Klein labeled them 'positions' rather than stages of psychological development. She also supported the move away from Freud's formulation of instincts and psychosexual energy toward one of object relations, namely the representations of the perception and experience of significant others. Similarly, transference was to be understood not only as a repetition of past or current relationships, but as evidence of relational patterns in the patient's current *internal* world.

In tandem with Klein, other analysts in Britain proposed ways in which significant early relationships, particularly between infant or young child and its mother, exerted a formative influence on the developing psyche. John Bowlby (1907–90), in particular, observed that children who had suffered a prolonged separation from their mother underwent a grief experience which predisposed them to a range of psychopathology in later life. Donald Winnicott (1896–1971), a pediatrician and analyst, proposed that a mother's attunement to her child, enabling him to feel psychologically 'held' and understood, was an essential ingredient for a stable sense of self. The American psychoanalyst Heinz Kohut advanced a similar concept, but highlighted the place of empathy whereby the mother functions as a 'self object' for the child.

Wilfred Bion, a student of Klein, suggested that the analyst functions as a 'container' into whom the patient projects their 'unprocessed' feelings and experiences; the analyst returns them later in a form accessible to him to work on. This experience is deemed to be crucial to the development of a person's ability to examine his or her own state of mind and that of others.

Michael Balint, an analyst at the Tavistock Clinic, worked along similar lines to Winnicott, focusing on the opportunity for the patient to 'regress' in the safety of the therapeutic relationship to a state of mind in which differentiating between patient and therapist may blur. The features of the encounter – its regularity, predictability, and the therapist's empathic attitude – creates circumstances for such regression which can then be used to examine and alter defense mechanisms.

These models have implications for practice in that the therapist expresses moment-to-moment empathic understanding of the patient's inner experiences and as this is repeated time and again the process promotes the evolution of a coherent identity.

Jacques Lacan (1901–81), the maverick French analyst, claimed a 'return to Freud,' his early work in particular, but through the prisms of semiotics and linguistics. These disciplines, he contended, do not see language as a value-free means to express ideas and convey meaning but as a system of signs that communicate symbolically tacit rules and power arrangements. Language imposes on the child awareness of a separateness from its mother who represents a fantasized internal object (the imaginary mother), in whose eyes the child mirrors itself in an attempt to achieve a state of psychological unity. Lacan's controversial proposals regarding variable duration of treatment and trainees themselves determining their competence to qualify as psychoanalysts led to his expulsion from the International Psychoanalytic Association, albeit with a dedicated following.

Humanistic experientially oriented schools of therapy became popular in the 1960s and 1970s, mainly in the US. Their chief features were: challenging patients with the way they avoid emotionally significant matters in the 'here-and-now'; increasing awareness of nonverbal aspects of communication; facilitating emotional arousal; and providing a forum in which patients were encouraged to experiment with new behaviors.

Some of these schools have incorporated aspects of psychoanalytic theory. Transactional analysis, for instance, makes playful use of the concept of ego states, represented as parent, adult, and child; primal scream therapy is predicated on heightened arousal of the purported emotional trauma of birth; and psychodrama encourages people to enact their conflicts by personifying various roles in their psychological lives.

The most influential humanistic school has been the client-centered therapy of Carl Rogers, although it has been absorbed into psychotherapy generally and not always with appropriate acknowledgment. Its premise is that if the therapist creates an atmosphere that is nonjudgmental, empathic, and warm, people can realize their potential for self-expression and self-fulfillment.

Feminist-based psychotherapies, still evolving since the 1980s, reflect a range of opinion from those which condemn Freud as a misogynist who deliberately recanted his discovery of the actuality of childhood sexual abuse, to those who appreciate his linkage of life experience, innate drives, and corresponding defense mechanisms in influencing vulnerability to psychopathology (Elliot, 1991; Appignanesi and Forrester, 1992). The latter point of view, echoing a broader debate within psychoanalysis of the respective roles of internal and external reality, has led some feminist therapists to stress social reality, and others to stress physical reality.

The Development of Other Modes of Psychotherapy

Our focus, hitherto, has been on psychotherapy of the individual patient. The second half of the twentieth century saw the evolution of treatments conducted with more than one

person: groups of strangers and families. In this section, we provide a brief account of the development of these two modes.

Although therapy of stranger groups was experimented on early in the century, it was not until World War II that major developments ensued. The exigencies of war were the spur in that the group format proved highly economical for dealing with huge numbers of soldier-patients. The Northfield Military Hospital in the UK was a center of remarkable innovation, led by psychoanalytically oriented therapists like Wilfred Bion and S.N. Foulkes. Bion's (1961) influence pervaded subsequent work at the Tavistock Clinic, while Foulkes (1965) was the founding father of the Institute of Group Analysis (both in London).

In the US, the move to the study of group process was spearheaded by social psychologists, particularly Kurt Lewin. A national center was established to train people in human relations and group dynamics. Participants from diverse backgrounds studied group functioning in order to act more effectively in their own work settings. Paralleling the human potential movement in the 1960s, the group movement transferred its focus from group to personal dynamics, and before long the encounter group movement had evolved with its thrust of promoting greater self-awareness and personal growth. Encounter groups became widespread during the 1960s and 1970s but after an initial fervor, declined both in terms of membership and appeal.

Formal group therapy under professional leadership then assumed a more prominent role. The most popular model was fathered by Irvin Yalom who drew upon an interpersonalist approach, one originally molded by Harry Stack Sullivan who proposed that personality is chiefly the product of a person's interaction with other significant people. Yalom pioneered the study of therapeutic factors specific to the group rather than following the pattern of transposing psychoanalytic or other theories from the individual setting. His *Theory and Practice of Group Psychotherapy* (Yalom, 1995) became exceedingly influential, attested to by the appearance of four editions.

Constrained perhaps by Western medicine's focus on the individual patient, psychiatry was slow to develop an interest in the family (Gurman and Kniskern, 1991). Scattered through Freud's writings are interesting comments about family relationships and their possible roles in both individual development and psychopathology. His description of processes like introjection, projection, and identification explained how individual experiences could be transmitted across the generations in a family. Influenced by the work in the UK of Anna Freud, Melanie Klein, and Donald Winnicott, the child guidance movement developed a model of one therapist working with a disturbed child and another with the parents, most often the mother on her own. The two clinicians collaborated in order to recognize how the mother's anxieties distorted her perception and handling of her child, which were added to the child's own anxieties.

Things took a different turn in the US. There, Ackerman (1958) introduced the idea of working with the family of a disturbed child using psychoanalytic methods in the 1950s. An interest in working with the family, including two or more generations, arose concurrently. Thus, Murray Bowen (1978) found that the capacity of psychotic children to differentiate themselves emotionally from their families was impaired by the consequences of unresolved losses, trauma, and other upheavals in the lives of parental and grand-parental generations.

Boszormenyi-Nagy and Spark (1984) also addressed this transgenerational theme by describing how family relationships were organized around a ledger of entitlements and obligations which conferred upon each participant a sense of justice about their position. This, in turn, reflected the experience in childhood of neglect or sacrifices for which redress was sought in adult life.

Bowen also introduced the principles of Systems Theory into his work but it was Salvador Minuchin, working with delinquent youth in New York, who highlighted the relevance of systems thinking to their interventions. The youngsters often came from emotionally deprived families, headed by a demoralized single parent (most often the mother) who alternated between excessive discipline and helpless delegation of family responsibilities to a child. Minuchin's Structural Family Therapy deploys a series of action-oriented techniques and powerful verbal metaphors which enable the therapist to join the family, and to reestablish an appropriate hierarchy and generational boundaries between the family subsystems (marital, parent/child, siblings).

Another major development took place in Palo Alto, California, where a group of clinicians gathered around the anthropologist Gregory Bateson (1972) in the 1950s. They noted that implicit in communication were *meta-communications*, which defined the relationship between the participants. Any contradiction or incongruence carried great persuasive, moral, or coercive force and formed part of what they labeled a 'double-bind'; they proposed this as a basis for schizophrenic thinking.

All these system-oriented views assume that the family is a system observed by the therapist. However, therapists are not value-neutral. They may take an active role in orchestrating change in accordance with a model of family functioning. Yet these models ignore therapists' biases as well as the relevance of their relationships with families. This probably reflected the determination of some American family therapists to distance themselves from psychoanalytic theory, and also led them to neglect the family's history, how it changed throughout the lifecycle, and the significance of past traumatic and other notable life events.

In response to these criticisms there was a move away from the problem-focused approach which had characterized most behavioral and communication views of psychopathology. The Milan school (1980) whose founders were psychoanalysts developed a new method of interviewing families in conjunction with observers behind a one-way screen formulating and then presenting to the family and therapist hypotheses about 'their' system.

Family therapists also began to consider that families might be constrained from experimenting with new solutions because of the way they had interpreted their past experiences or internalized explanatory narratives of their family, the expert's, or society at large. This led to a shift from considering the family as a social to a linguistic system.

The narrative a family conveys about their lives is a construction which organizes past experience in particular ways; other narratives are excluded. When a family with an ill

member talks to a professional, conversations are inevitably about problems (a problem-saturated description). The participants ignore times when problems were absent or minimal, or when they successfully confined problems to manageable proportions. A different story might be told if they were to examine the context that might have led, or could still lead, to better outcomes.

A number of narrative approaches have applied these concepts. Philosophically, they align themselves with post-modernism, which challenges the notion of a basic truth known only by an expert.

Many criticisms of systems approaches have been leveled including:

1. Disregard of the subjective and intersubjective experiences of family members.
2. Neglect of their history.
3. Denial of unconscious motives which affect relationships.
4. Although family members are reciprocally connected, the power they exert on one another is not equal; this is highlighted in the violence against women and in child abuse.
5. Inequality and other forms of injustice based on societal attitudes toward differences in gender, ethnicity, class, and the like, are uncritically accepted as 'givens'.
6. Minimizing the role of the therapeutic relationship, including attitudes members develop toward the therapist and her feelings toward them.

This critique has led to growing interest in integrating systems-oriented and psychoanalytic ideas, particularly those derived from object-relations theory. One variant is John Byng-Hall's (1995) synthesis of attachment theory, systems-thinking, and a narrative approach.

A further criticism of systems-oriented approaches is that they minimize the impact of external reality such as physical disability or biological factors, in the etiology of mental illness, and sociopolitical phenomena like unemployment, racism, and poverty. One result is the 'psychoeducational' approach, which has evolved in the context of the burden schizophrenia places on the family and the potential for its members to influence its course. This has led to a series of interventions including educating the family about the nature, causes, course, and treatment of schizophrenia; providing them with opportunities to discuss their difficulties in caring for the patient, and to devise appropriate strategies; and helping them to resolve conflict related to the illness, which may be aggravated by the demands of caring for a chronically ill person.

The Scientific Era

Systematic research in the psychotherapies was a low priority for many decades; instead, practitioners' interests focused on theory and technique. Investigation of the subject only took off in earnest in the early 1950s. A notable impetus was the critique by H.J. Eysenck (1952) in which he argued that the treatment of neurotic patients was no more effective than no treatment at all. Two-thirds of both groups showed improvement with time. In later reviews, Eysenck was even more damning: the effects of psychoanalysis in particular were minuscule. The attack led to much rancor and an extended battle between the psychoanalytic and behavioral camps (Eysenck featured prominently in the latter). Fortunately, a positive repercussion was the sense of challenge experienced by the analytic group. They had been riding high for several years, particularly in the US, and barely questioned whether their concepts and practice required scientific appraisal. Thus, although Eysenck's interpretation of the research literature was flawed and biased, he had stirred a hornet's nest.

Since the 1950s research has burgeoned and yielded much knowledge about whether psychotherapy works (outcome research) and how it works (process research). These developments were not without incident. Many therapists challenged the relevance of conventional research methodology to psychotherapy. A key argument was that the encounter between therapist and patient is unique, involving two people in a complex collaborative venture, and cannot be subject to the same form of scrutiny as occurs in the natural sciences. Moreover, the latter approach is necessarily mechanistic and reductionistic.

There is merit to the argument but actual research practice reveals that methodology can accommodate, at least in part, respect for the highly personal nature of psychological treatment. Sophisticated statistical procedures can also contribute to maintaining an appreciation that many characteristics in both patient and therapist are relevant, and they cannot be viewed as homogeneous groups. An illustration is the multidimensional measurement of outcome. Instead of restricting this to one or two variables only, several can be examined concurrently which together encompass the patients' internal and interpersonal world, e.g., quality of life, self-awareness, authenticity, self-esteem, target problems, and social adjustment.

Another criticism of outcome research is examining effectiveness without adequate treatment being given. Duration of research-bound therapy in fact is often much briefer than in customary practice because of funding constraints. A similar objection relates to the follow-up period usually set. A robust test of effectiveness entails examining outcome one or more years following the end of therapy in order to judge clinical projects independent of the therapist.

The Effectiveness of Psychotherapy

Several reviews have been conducted since the 1970s. A sophisticated method – meta-analysis – which relies on a rigorous statistical approach, points to psychotherapy overall generating benefits for patients who have been suitably selected. Encouragingly, better designed studies show positive results more commonly than inadequate ones. In one trail-blazing meta-analysis, levels of effectiveness were computed from 375 studies in which some 25 000 experimental and 25 000 controlled patients were tested (Smith et al., 1980). The average patient receiving psychological treatment of one kind of another was better off than 75% of those who were untreated – a clear demonstration of the beneficial effects of treatment in general.

With tens of 'schools' available, many of them claiming a distinctive approach, the obvious question arises as to

whether some are superior in producing benefit. This question of comparative effectiveness is complicated in that not only may 'schools' be compared but also specific procedures such as setting a time limit or not or conducting therapy individually or within a group. Notwithstanding these difficulties, considering research on comparative effectiveness is worthwhile. Several reviews show a consistent pattern – that 'everyone has won and must have prizes'. This was of course the judgment of a race handed down by the dodo bird in *Alice in Wonderland*. In the psychotherapy stakes, it appears that everyone has won too, a finding probably attributable to factors common to all therapeutic approaches. These factors, set out originally by Jerome Frank (1973), include a confiding relationship with a helping person, a rationale which provides an account of the patient's problems and of the methods for remedying them, instillation of hope for change, opportunity for 'success experiences' during treatment, facilitating emotion in the patient, and providing new knowledge, so promoting self-awareness. These 'nonspecific' factors comprise a significant theme in psychotherapy; they probably serve as a platform for benefits from all treatments.

Any consideration of effectiveness brings up the issue of harm. In other words, treatment may be for better or for worse. After a long gestation, the concept of a 'negative effect' attracted widespread attention from the 1970s (Hadley and Strupp, 1976). A growing sense of confidence perhaps permitted therapists to be more open to a potential harmful impact.

To distinguish between a patient becoming worse because of their intrinsic condition or following an adverse life event, a negative effect has been defined as deterioration directly attributable to treatment itself. Such a causal link is difficult to prove but genuine negative effects certainly do occur. The definitional difficulty, however, leads to estimates of prevalence ranging from rare to common. The type of therapy appears to influence the rate. Evidence points to worsening in about 5–10% of cases in psychotherapy generally. The reasons for deterioration are not well established although a common view is that patient factors probably contribute, particularly selecting people for treatments for which they are unsuited. In this situation, refining assessment, thus enhancing clinicians' ability to predict response to specific treatments, is deemed as helpful to reduce the casualty rate.

Another obvious facet is the therapist and/or technique. Here, inadequate training has emerged as salient, with poor judgment leading to inappropriate interventions. It has also been recognized that a proportion of therapists perform poorly because of their personality traits, no matter what their level of training or experience. In other words, the role of therapist does not suit all those who wish to practice. In a noteworthy study of different forms of encounter group, a substantial percentage of 'casualties' were produced by four leaders, who typically pummeled members to disclose personal information and express intense emotion.

During the half century of systematic research, attention has also been devoted to the processes that take place in the therapeutic encounter.

Process and outcome research are inevitably linked. If we can identify factors that promote or hinder effectiveness, we may be able to modify these and then note the result. The advent of recording techniques such as audio and video has facilitated studies of process and a wide range of observations of both verbal and nonverbal behavior, in both therapist and patient and their interaction, have been made. One illustration is the premise that a necessary condition for effective group therapy is group cohesiveness. It follows that anything enhancing cohesiveness could be advantageous. Compatibility between members has been proposed as pertinent and indeed been shown to relate to cohesiveness. Group therapy therefore could conceivably be more effective if, in selecting members, compatibility were taken into account. For example, a patient incompatible with all his peers would presumably not be placed in that group.

Research on process has been shown to be as salient as that on outcome since only with the study of what occurs in treatment can therapists appreciate its inherent nature and the factors for optimal improvement of participants. Diligent process research has provided solid foundations for establishing hypotheses about outcome.

We have dealt in general terms with the theme of psychotherapy research. The second half of the twentieth century has been a fertile period and seen much achieved; to do it justice is beyond our remit. The interested reader is recommended to consult the four editions of the *Handbook of Psychotherapy and Behavior Change* (Bergin and Garfield, 1994) which has served the field in distilling work done and providing a critique of its quality.

Psychotherapy Integration

Abstract

Psychotherapy integration is characterized by a desire to look across and beyond theories to see how patients can benefit from multiple ways of conducting psychotherapy. Formal ideas on synthesizing therapies appeared in the 1930s, but it is only since the 1980s that integration developed formally. A number of mutually reinforcing motives that have fostered the recent growth of integration are reviewed. The most frequent integrative pathways – technical eclecticism, theoretical integration, common factors, and assimilative integration – are considered and compared. Although integration faces several obstacles, its research support and clinical popularity suggest that it will probably constitute the future of the discipline.

Psychotherapy integration is characterized by dissatisfaction with single-school approaches and a concomitant desire to look across school boundaries to see how patients can benefit from other ways of conducting psychotherapy. Although various labels are applied to this international movement – including integration, eclecticism, rapprochement, convergence, responsiveness, and prescriptionism – the goals are similar indeed. The ultimate goal is to enhance the efficacy and applicability of psychotherapy.

Applying identical psychosocial treatments to all patients in all circumstances is now recognized as inappropriate and perhaps unethical. Different folks require different strokes. The efficacy of psychotherapy will be enhanced by tailoring it to the unique needs of the client, not by imposing procrustean methods on unwitting consumers of psychological services. The integrative mandate is embodied in Gordon Paul's (1967) iconic question: *What* treatment, by *whom*, is most effective for *this* individual with *that* specific problem and under *which* set of circumstances?

Any number of indicators attests to the popularity of psychotherapy integration. *Eclecticism*, or the increasingly favored term *integration*, is the first or second most frequent theoretical orientation of English-speaking psychotherapists (e.g., Norcross and Karpiak, 2012). It is less popular but increasing in other countries. Leading psychotherapy textbooks routinely identify their theoretical persuasion as integrative, and an integrative chapter is regularly included in compendia of treatment approaches. The publication of books that synthesize various therapeutic concepts and methods continues unabated; they now number in the hundreds. Handbooks on psychotherapy integration have now been published in at least a dozen countries (e.g., Norcross and Goldfried, 2005; Stricker and Gold, 2006).

The prevalence of psychotherapy integration can be ascertained directly by assessing endorsement of the integrative orientation (as noted in this article) or gleaned indirectly by determining endorsement of multiple orientations. For example, in a study of British counselors, 87% did *not* take a pure-form approach to psychotherapy (Hollanders and McLeod, 1999). In a study of clinical psychologists in the United States, for another example, fully 90% embraced several orientations (Norcross and Karpiak, 2012). Very few contemporary therapists adhere exclusively to a single therapeutic tradition.

The Historical Context

Integration as a point of view has probably existed as long as philosophy and psychotherapy. In philosophy, the third-century biographer Diogenes Laertius referred to an eclectic school that flourished in Alexandria in the second century (Lunde, 1974). In psychotherapy, Freud consciously struggled with the selection and integration of diverse methods. As early as 1919, he introduced psychoanalytic psychotherapy as an alternative to classical psychoanalysis in recognition that the more rarified approach lacked universal applicability (Liff, 1992).

However, the discipline of psychotherapy historically has been organized around singular and rival theories, such as psychoanalysis, existentialism, behaviorism, and family systems. In the infancy of the field, therapy systems, like battling siblings, competed for attention and affection in a 'dogma eat dogma' environment. Clinicians traditionally operated from within their own particular theoretical frameworks, often to the point of being blind to alternative conceptualizations and potentially superior interventions.

Formal ideas on synthesizing the psychotherapies appeared in the literature in the 1930s (Goldfried et al., 2005). Thomas French (1933) stood before the 1932 meeting of the American Psychiatric Association and drew parallels between certain concepts of Freud and of Pavlov. In 1936, Sol Rosenzweig published an article that highlighted commonalities among various systems of psychotherapy. These and other early attempts at integration, however, were largely theory driven and empirically untested.

If not conspiratorially ignored altogether, these precursors to integration appeared only as a latent theme in a field organized around discrete theoretical orientations. Although psychotherapists secretly recognized that their orientations did not adequately assist them in all they encountered in practice, a host of political, social, and economic forces – such as professional organizations, training institutes, and referral networks – kept them penned within their own theoretical schoolyards and typically led them to avoid clinical contributions from alternative orientations.

Systematic integration was probably inaugurated in the modern era by Frederick Thorne (1957), who is credited with being the grandfather of eclecticism in psychotherapy. Persuasively arguing that any skilled professional should

come prepared with more than one tool, Thorne emphasized the need for clinicians to fill their toolboxes with methods drawn from many theoretical orientations. He likened psychotherapy at that time to a plumber who used only a screwdriver. Like such a plumber, inveterate psychotherapists applied the same treatment to all people, regardless of individual differences, and expected the patient to adapt to the therapist rather than vice versa.

Since the mid-1980s, psychotherapy has witnessed a decline in ideological struggle and the stirrings of rapprochement. The theoretical substrate of each system is undergoing intensive reappraisal, as psychotherapists acknowledge the inadequacies of any one system and the potential value of others. Distinctive of the present era is the tolerance for and assimilation of formulations that were once viewed as deviant, or even heretical.

Integration Defined

As the field of psychotherapy has matured, integration has emerged as a dominating force. The dramatic interest in psychotherapy integration has crystallized into a formal movement, or, more dramatically, a 'metamorphosis' in mental health (London, 1988). At the very least, integration represents a revolutionary departure from decades of school-ism.

Psychotherapy integration is characterized by dissatisfaction with single-school approaches and a concomitant desire to look across and beyond school boundaries to see what can be learned – and how patients can benefit – from other ways of thinking about psychotherapy and behavior change. The ultimate outcome of doing so, which is not yet fully realized, is to enhance the effectiveness, efficiency, and applicability of psychotherapy.

As with many new movements, integration has been plagued by confusing vocabulary and multiple variants. Various labels are applied to the movement, but *psychotherapy integration* has emerged as the overarching consensual term. Similarly, a plethora of integrations have been advanced: combining different therapy formats (such as individual, family, and group therapies), blending self-help and psychotherapy, integrating pharmacotherapy and psychotherapy, synthesizing research and practice, integrating Western and Eastern perspectives, and so on. This article confines itself to the traditional and primary meaning of integration as the blending of diverse theoretical orientations or schools of psychotherapy.

Reasons for Recent Growth

A number of interacting, mutually reinforcing motives have fostered the recent growth of integration (Prochaska and Norcross, 2014):

- *Proliferation of therapies*. Which of 500-plus therapies should be studied, taught, or bought? The hyperinflation of brand-name therapies has produced narcissistic fatigue: "With so many brand names around that no one can recognize, let alone remember, and so many competitors doing psychotherapy, it is becoming too arduous to launch still another new brand" (London, 1988: pp. 5–6). This might also be called the 'exhaustion theory' of integration: Peace among warring schools is the last resort.
- *Inadequacy of any single theory for all patients and problems*. No therapy or therapist is immune to failure. It is at such times that experienced practitioners often wonder if the clinical methods from orientations other than their own might have been more effective. Underlying the ecumenical spirit is the stark realization that narrow conceptual positions and limited clinical methods cannot begin to address the diverse needs and disorders of our patients. Clinical realities have come to demand a more flexible, if not integrative, perspective.
- *External socioeconomic contingencies*. Psychotherapy has experienced mounting pressures from not easily disregarded sources such as policy makers, informed consumers, and insurance companies. Everyone is demanding hard research evidence of effective treatments. Unless they demonstrate accountability, psychotherapists stand to lose prestige, customers, and money. Attacks from outside the mental health professions have started to propel them together. There is something to be said for having the different therapies 'hang together' rather than 'hang separately.'
- *Ascendancy of short-term, problem-focused treatments*. The brief problem focus has brought divergent therapies closer together and has created variations of different treatments that are more compatible with each other. Integration, particularly in the form of eclecticism, responds to the pragmatic time-limited injunction of "whatever therapy works better – and quicker – for this patient with this problem."
- *Opportunities for therapists to observe and experiment with various treatments*. The establishment of specialized clinics for the treatment of specific disorders – personality disorders, trauma, and eating disorders, to name a few – has afforded exposure to other therapies, and stimulated some therapists to consider the other therapies more seriously. Treatment manuals have also induced an informal version of 'theoretical exposure': Previously feared and unknown therapies were approached gradually, anxiety was dissipated, and the previously feared therapies were integrated into the clinical repertoire.
- *Recognition that therapeutic commonalities heavily contribute to treatment outcome*. Only about 8–12% of outcome is generally accounted for by the specific treatment method. Therapeutic success can be best predicted by common elements of psychotherapy, such as the contributions of the patient, the therapy relationship, and the facilitative qualities of the therapist.
- *Development of professional societies for integration*. The creation of professional networks has been both a consequence and cause of interest in psychotherapy integration. Several organizations, principally the Society for the Exploration of Psychotherapy Integration, have brought together integration enthusiasts through conferences, networking, and journals. Integrationists now have a professional home.

These factors speak to the entire field of psychotherapy moving toward integration. But what motivates individual

therapists to embrace integration? Robertson (1979) identified six personal factors that facilitate the acquisition of an eclectic or integrative stance. The first is a lack of pressure in training to adopt a doctrinaire position and the absence of a charismatic figure to emulate. The second factor, which has been substantiated by research (Norcross, 2005), is length of clinical experience: As therapists encounter complex clients and problems over time, they are more likely to reject a single theory as too simple. A third factor is the extent to which doing psychotherapy is making a living or making a philosophy of life; Robertson asserts that integration is more likely to follow the former.

The remaining three factors are personality variables: an obsessive–compulsive desire to give order to all the interventions of the therapeutic universe, a maverick temperament to move beyond a theoretical camp, and a skeptical attitude toward the status quo. These personality traits are frequently found in the personal histories of prominent integrative therapists (e.g., see, Goldfried, 2001).

Pathways to Integration

There are numerous pathways toward the integration of the psychotherapies. The four most popular routes appear to be technical eclecticism, theoretical integration, common factors, and assimilative integration. Research (Norcross et al., 2005) reveals that each is embraced by a considerable number of self-identified eclectics and integrationists (19–28% each). All four attempt to look beyond the confines of single theories, but they do so in rather different ways and at different levels.

Technical eclecticism seeks to improve our ability to select the best treatment methods for the person and the problem. This search is guided primarily by research on what specific methods have worked best in the past with similar problems and patient characteristics. Eclecticism focuses on predicting for whom interventions will work; its foundation is actuarial rather than theoretical. Exemplars of eclecticism include Lazarus's (1967, 1989) influential multimodal therapy and Beutler et al.'s (2000) systematic treatment selection.

Technical eclectics use procedures drawn from different therapeutic systems without necessarily subscribing to the theories that spawned them, whereas theoretical integrationists draw their concepts and techniques from diverse systems that may be epistemologically or ontologically incompatible. For technical eclectics, no necessary connection exists between conceptual foundations and techniques. "To attempt a theoretical rapprochement is as futile as trying to picture the edge of the universe. But to read through the vast amount of literature on psychotherapy, *in search of techniques*, can be clinically enriching and therapeutically rewarding" (Lazarus, 1967: p. 416).

In *theoretical integration*, two or more therapies are united with the hope that the hybrid result will be better than the constituent therapies alone. As the name implies, there is an emphasis on integrating, or at least bridging, the underlying theories of psychotherapy along with the techniques from each. Wachtel's (1977) integration of psychoanalysis and behaviorism, as well as Prochaska and DiClemente's transtheoretical (or stages of change) model (Prochaska et al., 1994), illustrate this path. Some would also add here the infusion of acceptance and mindfulness of the 'third-wave' therapies to cognitive-behavior therapy.

Theoretical integration involves a commitment to a conceptual or theoretical creation beyond a technical blend of methods. The goal is to create a conceptual framework that synthesizes the best elements of two or more therapies. Integration aspires to be more than a simple combination; it seeks an emergent theory that is more than the sum of its parts.

The *common factors* approach seeks to identify core ingredients shared by different therapies with the eventual goal of creating more parsimonious and efficacious treatments based on those commonalities. This search is predicated on the belief that commonalities are more important in accounting for therapy success than the unique factors that differentiate among them. The research-informed models of Jerome Frank (1973) and Bruce Wampold (2001) exemplify the common factors route.

Literature reviews have discovered that the most consensual commonalties across theories are the development of a therapeutic alliance, opportunities for catharsis, acquisition and practice of new behaviors, and clients' positive expectancies (Grencavage and Norcross, 1990).

Marvin Goldfried (1980), a leader of the integration movement, argued,

> [to] the extent that clinicians of varying orientations are able to arrive at a common set of strategies, it is likely that what emerges will consist of robust phenomena, as they have managed to survive the distortions imposed by the therapists' varying theoretical biases. (p. 996)

In specifying what is common across orientations, we may also be selecting what works best among them.

The fourth and most contentious pathway is *assimilative integration*, which entails not only a firm grounding in one system of psychotherapy but also a willingness to selectively incorporate (assimilate) practices and views from other systems (Messer, 2001). In doing so, assimilative integration combines the advantages of a single, coherent theoretical system with the flexibility of a broader range of technical interventions from multiple systems. A cognitive therapist, for instance, might use the gestalt two-chair dialogue or a systemic paradoxical directive in an otherwise cognitive course of treatment.

To its proponents, assimilative integration is a realistic way station on the path to a sophisticated integration; to its detractors, it is a waste station of people unwilling to commit themselves to a full evidence-based eclecticism. Both camps agree that assimilation is a tentative step toward full integration: Most therapists gradually incorporate parts and methods of other approaches once they discover the limitations of their original approach. Inevitably, therapists gradually integrate new methods into their home theory.

These four integrative pathways are not mutually exclusive, of course. No technical eclectic can disregard theory, and no theoretical integrationist can ignore technique. Without some commonalities among different schools of psychotherapy, theoretical integration would prove impossible. And even the most ardent proponents of common factors cannot practice

'nonspecifically' or 'commonly' on their own; specific methods must be applied.

While the field has not settled on a single route to the integrative summit, it has firmly rejected *syncretism* – uncritical and unsystematic combinations. This haphazard approach is primarily an outgrowth of pet techniques and inadequate training. It is an arbitrary blend of methods without systematic rationale or empirical verification (Eysenck, 1970). Psychotherapy integration, by contrast, is the product of years of painstaking training, research, and experience. It is integration by design, not default; that is, clinicians competent in several therapeutic systems who systematically select treatment methods and therapeutic relationships on the basis of outcome research and patient need.

Research Support

The research support for the effectiveness of psychotherapy integration comes in several guises. First and most generally, the entire body of empirical research on psychotherapy informs treatment selection. A genuine advantage of being an eclectic is the vast amount of research attesting to the efficacy of psychotherapy and pointing to its differential effectiveness with certain types of disorders and patients. Of course, this research translates into improved outcomes only if the psychotherapist is aware of, and adheres to, the research conclusions. In this respect, a natural affinity has arisen between integration and evidence-based practice.

Controlled outcome research has been conducted on integrative therapies. A comprehensive review of the adult literature (Grawe et al., 1998) located 22 controlled studies covering 1743 patients treated with diverse therapies described as eclectic: either explicitly no school connection or multiple combinations of methods. In 9 of the 13 comparisons, the eclectic therapy outperformed the control treatment in terms of symptom relief, and in four of the six comparisons in terms of subjective well-being. A comprehensive meta-analysis of the child literature (Weisz et al., 1995) located 20 controlled studies on mixed treatments, which produced a respectable effect size of 0.63 compared to control conditions, a moderate to large effect. The interpretative problem, however, is that we possess little understanding of what these multifarious treatments represent.

A corrective strategy would be to assess whether more complex and integrative treatments outperform simpler and single-theory treatments. One clever meta-analysis did just that (Stevens et al., 2007). In 14 studies, more complex therapies were compared with less complex treatments. The effect size for the complex therapies was slightly higher (0.15), which translates into an increase in improvement rates from 66 to 81%.

More specifically, programmatic research supports the effectiveness of matching different treatment methods and relationship stances to different people. All the patient qualities that predict differential effectiveness have not yet been determined, but meta-analytic research demonstrates that tailoring therapy to patients' transdiagnostic characteristics demonstrably improves the outcome of psychosocial treatments (Norcross, 2011).

For example, matching therapist directiveness to the client's degree of resistance improves therapy outcome. In 80% of the studies, clients presenting with high resistance benefit more from self-control methods and minimal therapist directiveness, such as in motivational interviewing. By contrast, clients with low resistance benefit more from therapist directiveness and explicit guidance. This strong, consistent finding can be expressed as a large effect size averaging 0.76 (Beutler et al., 2011). The clinical implication is to match the level of the therapist's directiveness to the patient's level of resistance.

For another example, 30 years of research in behavior change and psychotherapy converge in showing that different processes of change are differentially effective in certain stages of change (precontemplation, contemplation, preparation, action, and maintenance). A meta-analysis (Rosen, 2000) of 47 cross-sectional studies examining the relationships among the stages and the processes of change showed large effect sizes ($d = 0.70$–0.80). Methods associated with psychoanalytic and insight-oriented psychotherapies are most useful during the earlier precontemplation and contemplation stages. Existential, cognitive, and interpersonal therapies are particularly well suited to the preparation and action stages. Behavioral, exposure, and solution-focused therapies are most useful during action and maintenance. Each therapy system has a place, a differential place, in the big picture of behavior change (Norcross et al., 2011).

These and other research-supported prescriptive matches improve the effectiveness of psychotherapy, integrative and otherwise. How directive should a therapist be? Which treatment approach – insight oriented or symptom focused – works better? In the integrative tradition, it depends upon the particular client.

Future Directions

Transtheoretical dialogue and cross-fertilization fostered by the integrative spirit have produced new ways of thinking about psychotherapy and researching behavior change. This closing section outlines probable directions of the integration movement.

First and foremost, psychotherapy integration, in some guise, will likely emerge as the Zeitgeist. A dispassionate panel of psychotherapy experts portended its escalating popularity in the coming decade (Norcross et al., 2013). The integrative fervor will apparently persist well into the twenty-first century.

Integrationists will increasingly attend to the potential obstacles and tradeoffs of the process of integration. These will include establishing ambitious training programs and processes that ensure student competence in multiple theories and interventions, an unprecedented task in the history of psychotherapy; acknowledging the underlying epistemological and ontological differences embodied by the disparate theories of psychotherapies, which precludes facile integration; and addressing the language problem that confounds understanding of disparate jargons and, in some cases, leads to active avoidance of theoretical constructs.

At the same time, psychotherapy integration will evolve past its initial step of widening therapeutic horizons and embracing

multiple treatments. The next step is to specifically know when and where to use these multiple techniques and theories in order to enhance outcomes. While the emphasis has been traditionally on matching Treatment X to Disorder Y, the integration movement is more and more committed to adapting Therapeutic Relationship X to Person Y. Paralleling the notion of treatment of choice in terms of techniques, clinicians will determine the relationship of choice in terms of interpersonal stances for individual clients and their singular situations. Such tailoring or adapting will occur on the basis of diagnostic and especially cross-diagnostic considerations, such as the patient's preferences, culture, coping style, personality traits, and stage of change (Norcross, 2011).

Conclusion

Integration can take several different paths – theoretical integration, technical eclecticism, common factors, and assimilative integration – but it consistently searches for new ways of conceptualizing and conducting psychotherapy that go beyond the confines of single schools. Integration encourages practitioners and researchers to examine what other therapies have to offer, particularly when confronted with difficult cases and therapeutic failures. Rival therapy systems are increasingly viewed not as adversaries, but as welcome partners (Landsman, 1974); not as contradictory, but as complementary.

Integrative psychotherapies are intellectually vibrant, clinically popular, and, when evaluated, demonstrably effective. Integration converges with the evidence-based movement in emphasizing that different people require different solutions and that these solutions increasingly can be selected on the basis of empirical research. It offers the evidence, flexibility, and responsiveness to meet the multifarious needs of individual patients and their unique contexts. For these reasons, integration will assuredly be a therapeutic mainstay of the twenty-first century. In that ideal future, psychotherapy will be defined not by its theoretical orientations or brand names but by its effectiveness and applicability (Norcross and Beutler, 2013).

Abstract

Psychotherapy process research examines the interactions and experiences of patients and therapists in psychosocial mental health treatments. Early psychotherapy researchers differentiated between 'outcome' studies that focus on the impact of treatment on patients, and 'process' studies that examine the events of therapy. Process studies typically focus on verbal and nonverbal communications between patients and therapists in sessions, treatment methods, qualities of the patient–therapist relationship, and experiences of patients and therapists during and between therapy sessions. This article discusses basic concepts and methods of process research, the main findings linking process to outcome, and new areas of research.

Psychotherapy process research is the scientific study of what happens in psychotherapy. It involves the precise, systematic, and controlled observation and analysis of the events that constitute psychotherapy. The basic elements of psychotherapy are simple – a patient, the distress or illness experienced by the patient, a therapist, and the treatment that the therapist provides – but psychotherapy occurs in a wide variety of forms and settings, involves a wide diversity of practitioners, and is conducted according to widely divergent theories about the causes and cures of psychological illness and distress. Since psychotherapy process research takes all these variations as its subject, a brief overview of the field it studies may serve as an introduction.

Psychotherapy

The forms of psychotherapy most commonly include 'individual therapy' (one therapist with one patient), 'couple therapy' (one therapist with two patients who are married or partners in a relationship), 'family therapy' (one or more therapists with members of a multigenerational family), and 'group therapy' (one or two therapists with several patients who were previously strangers).

The settings in which psychotherapy is practiced include community mental health centers; private professional practices; university or college counseling centers, research clinics, and psychotherapy training centers; inpatient or outpatient psychiatric facilities; social work agencies; corporate employee assistance programs; and church-sponsored counseling programs.

The practitioners of psychotherapy are similarly diverse in background and training. Psychotherapists are not members of a single profession, but instead have typically been trained in one of the following: clinical or counseling psychology, clinical social work, psychiatry, psychosomatics, general medicine, psychiatric nursing, marital counseling or other counseling specialties, or pastoral care. The level of involvement of different professions in psychotherapeutic practice, and their relative standing vis-à-vis one another, varies from country to country.

Still, the most striking difference among psychotherapeutic practitioners is the diversity of theoretical models used in guiding their clinical work. Broadly, these models include variations on the following: analytic and psychodynamic theories; behavioral, cognitive, and cognitive-behavioral procedures; existential, experiential, and humanistic approaches; hypnotherapy; and interpersonal, relational, and family systems orientations. Initially, these theories formed the bases for rival 'schools' of psychotherapy. More recently, many therapists have adopted an eclectic or integrative mode of practice, seeking to broaden their effectiveness by combining the strengths of different models or using those that seem to suit the needs of particular clients (e.g., Goldfried et al., 2011). The increasingly multicultural nature of modern countries has also created pressure on practitioners to adapt their traditional treatment models to fit the needs and circumstances of particular socioeconomic, cultural, ethnic, and linguistic groups (Zane et al., 2004).

For simplicity in discussion, all the mental health practices based on interpersonal influence through the application of psychological methods to improve the mental health and emotional well-being of distressed or troubled persons will be termed psychotherapy – whether their practitioners call it psychotherapy, therapeutic counseling, psychoanalysis, behavior modification, growth facilitation, or some other term. Similarly, all the mental health workers who engage in these practices professionally will be referred to as psychotherapists, and those whom they treat will be referred to as patients.

Psychotherapy Research

The scientific study of psychotherapy emerged as a field of academic research in the mid-twentieth century, following World War II, through the pioneering work of teams of investigators such as those led by Carl Rogers at Ohio State University and the University of Chicago, Jerome Frank at Johns Hopkins University, and researchers at the Menninger Clinic. Readers may consult Castonguay et al. (2010) for valuable biographical accounts of these pioneers and other later significant contributors.

During the decades since the 1950s and 1960s, the field of psychotherapy research continued to grow at an increasing pace

and volume of studies (Orlinsky and Russell, 1994; Strupp and Howard, 1992) to the present (cf Norcross et al., 2011: chapters 10–12). Within the field, a distinction soon grew up between two kinds of research, depending on the principal focus: 'psychotherapy outcome research,' which studied the impact of therapy on patients after treatment concludes (called efficacy or effectiveness, respectively, based on whether treatment was conducted in laboratory or naturalistic settings); and 'psychotherapy process research,' which focused instead on the interactions and experiences of patients and therapists during therapy.

Even from the outset, however, some studies included measures both of process and outcome, and over time 'psychotherapy process–outcome research' has become an increasingly important focus of inquiry because such studies link specific aspects and kinds of events in therapy to their immediate and long-term impact. After an extensive review of three decades of findings from process–outcome research, Orlinsky and Howard (1986) presented an integrative conceptualization broadly based on a twofold distinction: first, between therapeutic processes (the observable and experienced aspects and events of therapy) and their functional contexts (the psychological, social, and cultural circumstances in which therapy takes place); and second, between the states of these contexts as they exist prior to therapy or to specific moments of process within therapy (e.g., before a particular intervention) – the 'inputs' or determinants of process – and those contexts as they exist subsequent to specific moments of therapy process (e.g., a patient's experience of insight) or to the course of therapy as a whole – the 'outputs' or consequences of therapy process.

The inputs or determinants of process include, most immediately, the psychological characteristics and personal problems that patients bring to therapy, as well as the theoretical treatment model that therapists apply in therapy, their professional skills in doing so, and their personal manner and presence with patients. Less directly, but of potential importance, the inputs or determinants of process would also include the social characteristics of the treatment setting; the nature and state of the mental health service delivery system of which it is a part; the current economic, political, and societal pressures and stressors upon them; and the prevailing cultural standards regarding selfhood, well-being, and personal maturity (e.g., Kirmayer, 2007).

The outputs or consequences of therapy processes include, most immediately, the changes that occur (usually positive but possibly negative) in the patient's life and personality (clinical 'outcome'); they also include, viewed in this broad framework, the impact of therapeutic events on the professional and personal life of the therapist (e.g., growth in experience and expertise vs emotional depletion and burnout), and, less directly, the aggregate influence of patients' and therapists' experiences on social institutions and cultural values.

This conceptualization of therapy as involving contextual influences, therapeutic processes, and contextual consequences has served for nearly two decades to integrate the findings of many research studies into a coherent body of knowledge (Orlinsky et al., 1994; Orlinsky and Howard, 1986; Orlinsky et al., 2004). It was called the 'generic model of psychotherapy' to reflect its use as a framework that can encompass and can be used to compare the varied types or species of psychotherapy (e.g., Orlinsky and Howard, 1995). Between the contextual inputs or determinants and the contextual outputs or consequences lies the complex set of psychological interactions and transformations that comprise the psychotherapeutic process. The generic model includes these as specific variables grouped in the following process categories: (1) the therapeutic contract or organizational aspect of process (understanding between participants with respect to treatment goals, setting, schedule, etc.); (2) therapeutic operations, the technical–instrumental aspect of process (participants' engagement in specific treatment interventions, in their roles as therapist and patient); (3) the therapeutic bond or interpersonal aspect of therapy (the quality of rapport and feelings of participants toward one another as persons); (4) psychological self-relatedness, the reflexive-intrapersonal aspect of process (the self-awareness, self-management, and self-feelings of the participants as therapy proceeds); (5) in-session impacts, the clinical aspect of process (e.g., enhanced insight and morale for patients and sense of efficacy and work satisfaction for therapists); and, as these unfold over time, (6) the sequential process patterns, the temporal aspect of therapy (including interaction sequences within sessions, between sessions, and over the course of treatment).

Before embarking on a study, researchers who would observe and analyze therapeutic process must make a number of decisions about framing and focusing their studies. Framing a psychotherapy process study entails decisions about the location of the phenomenon (where to look), the temporal unit of observation (how long to look), and the observational perspectives to be employed (from which angle to look). Focusing the study involves making decisions about the facets and phases of therapeutic process to assess (which 'variables' to measure).

Process Research Frames

Location

While therapeutic process may be defined abstractly in terms of psychological interactions and transformations, process researchers have differed over where and how they can best be observed. Initially, most researchers viewed therapeutic process as consisting of the externally observable interactions and communications between the patient and therapist during their therapy sessions. Subsequently, many also included post-session reports by patients and therapists about their experiences during the sessions; and, more recently, researchers have come to recognize that therapy also occurs actively between therapy sessions, whether by design in the form of 'homework assignments' (Kazantzis and L'Abate, 2007) or spontaneously in the reminiscences, reflections, and imaginings of patients and therapists about their therapy and one another (e.g., Hartmann et al., 2011).

A further difference in view is whether therapeutic process includes all the events that occur during and between therapy sessions or just those that are specifically directed toward patient improvement. The former view, which is largely descriptive and discovery-oriented, appeals primarily to researchers who assume that all the factors that produce positive or negative patient outcomes are not yet known. The latter

view focuses specifically on incident of in-session impact ('change events') and tends to appeal to investigators who usually hold, and seek to test, some particular theoretical conception of therapy (e.g., Barber et al., 2013; Elliott et al., 2013; Emmelkamp, 2013; Hollon and Beck, 2013). To distinguish clearly between these contrasting but somewhat overlapping views, the former will be called therapy session process and the latter therapeutic change process.

Temporal Units

The concept of process refers most generally to activities and events that proceed or evolve over time – but some activities and events proceed or evolve so rapidly, or so slowly, that they normally cannot be noticed. Examples of the former are the interactions that physicists observe among subatomic particles or, more familiarly, the rapid projection of still photographs that one does not notice separately but experience sequentially as 'moving' pictures. Examples of the latter include the geological raising of mountain ranges by the gradual collision and subduction of tectonic plates, and their imperceptible erosion by millennia of wind and rain. The point is commonplace but basic and relevant. To be observed at all, therapeutic process must be framed within the temporal span of human consciousness, but there is still a range of noticeable rates at which process events occur. The researcher may choose to examine very brief events, like changes in facial expression or vocal intonation; somewhat longer events, like the statement by one person of a coherent line of thought involving several sentences, or dialogue between patient and therapist on a particular topic that includes successive statements by each; still longer events, like the quality of whole therapy sessions; even longer events, like the opening, middle, and closing phases of an extended course of treatment; or the clinical history of successive psychotherapies over a patient's life. The temporal units or frames of reference that researchers select for study inevitably determine the kind of therapeutic events they can observe, and the descriptions of therapeutic process they give.

Observational Perspectives

Any complex event can be viewed from several angles, and each observational perspective has the potential to reveal a different aspect of the event. In psychotherapy, there are two distinct perspectives, that of patients and that of therapists (e.g., Orlinsky and Howard, 1975), who as participant observers experience the events of therapy directly but from separate vantage points. To these, psychotherapy research has added the perspectives of nonparticipant observers by relying on clinical raters who are not part of the events being observed and whose view of therapeutic process is generally mediated by audio or video recordings of therapy sessions or transcriptions of the verbal content of sessions. Participant observers have not only a 'first-hand' and 'inside' but also fleeting view of the events they experience. They have direct awareness of their own thoughts, feelings, and intentions, and immediate impressions of their own and others' behaviors, but these are typically organized around their goals in action. By contrast, nonparticipant observers gain only 'second-hand' knowledge of therapeutic process, and can only infer the covert internal states of the participants. However, they have the advantage of being able to carefully and repeatedly study the recorded events without the situational pressures to respond that participants experience.

Researchers may use, and have used, one, two, or all these observational perspectives in their studies; depending on their interests and the questions they investigate. It should not seem strange to researchers, or an indication of methodological weakness, if observers who view therapeutic phenomena from different perspectives often produce discrepant observations, since those discrepancies may validly reflect the inherent complexity of social phenomena.

Process Research Focus

When undertaking a study of therapeutic process, researchers understand that they are dealing with a set of events that is too complex to be observed in its entirety. Consequently, they must simplify the focus of the study on a few specific facets of therapeutic process, which are the 'variables' to be studied. For the simplification to be meaningful, these variables must be defined in terms of a theoretical model that will be understood and accepted by other researchers.

Research Variables

Traditionally, the variables examined in psychotherapy process studies have been differentially defined according to whether they focus on the task-instrumental or technique aspect of therapist and patient behavior (referred to generically as 'therapeutic operations'), or focus instead mainly on the social–emotional or relational aspect of therapist and patient behavior (generically encompassing both the 'therapeutic bond' and consensus with respect to 'therapeutic contract').

Task-instrumental behaviors include the interventions that clinical theories suggest are helpful to patients: for example, interpretation of the patient's free associations, dreams, or resistances and transference in psychodynamic therapies; empathic reflection of feeling in person-centered therapy; or relaxation training to counteract phobic anxiety in cognitive-behavioral therapies. Research variables often focus on the content, timing, skillfulness, and appropriateness with which therapists use these techniques. Other variables may focus on the patient's cooperative or resistant response to therapist interventions and on the specific effects of those interventions ('in-session impacts'). Research procedures focused on instrumental aspects of therapeutic process include those described in Greenberg and Pinsof (1986: chapters 2–8, 14).

Researchers have also very extensively studied varied aspects and effects of the relationship between patient and therapist (Horvath et al., 2011; Norcross, 2011). Relationship variables generally focus on the interpersonal manner (as distinct from the task-instrumental content) of therapist's and patient's interactions during sessions; their attitudes and feelings toward one another; and their respective contributions to the formation and development of a therapeutic alliance. In this area too, researchers espousing different theoretical frameworks have focused on the specific relationship qualities suggested by their

respective orientations. Thus, researchers influenced by psychoanalytic theory have focused on issues related to the concept of transference (Levy and Scala, 2012), such as the 'core-conflictual themes' expressed in patients' personal relationships (Luborsky and Crits-Christoph, 1997), and the therapist's countertransference (Gelso and Hayes, 2007). Others, influenced by client-centered theory, have focused on therapist-offered relationship conditions such as genuineness, empathy, and positive regard (e.g., Elliott et al., 2011). Social psychological theories of interpersonal behavior have provided another conceptual approach to research on relationships, emphasizing the reciprocal influences between patient and therapist, focusing on dimensions of behavior such as acceptance vs rejection and control vs autonomy (e.g., Brehm and Smith, 1986). However, given the advent of technological developments such as computer-administered therapeutic programs and text message interventions, which do not involve direct face-to-face interaction with a clinician, the concept of therapy as an essentially interpersonal process may need to be extended. Researchers have also given special attention to the importance of repairing 'alliance ruptures,' which may occur when therapists misunderstand or lack empathy for what is troubling their patients (Safran et al., 2011). Useful procedures for studying therapeutic relationships are described by their proponents in Greenberg and Pinsof (1986: chapters 9–12, 15).

Research Methods

The events of psychotherapy occur in a series of meetings between patient and therapist called therapy sessions. The most directly observable aspects of those events consist of conversation. In some types of therapy, conversation may be supplemented by having patients engage in activities or exercises (e.g., role-play) designed to provide significant learning or corrective emotional experiences. Given the prominence of verbal and nonverbal communications, researchers have relied on audio- and videotapes of therapy sessions to record the events of therapy. Recording and replay technology have not only provided investigators with voluminous records for detailed examination from an 'external' or nonparticipant observational perspective, but also constrained them to concentrate on temporal units that have generally been briefer than whole sessions, and sometimes no longer than one complete statement or interchange between a patient and therapist. But, conversation is only the outward aspect of therapeutic events. The inner side of process is comprises patients' and therapists' experiences of themselves and one another during their sessions, and during the imagined conversations or fantasy interactions that they may have in the times between sessions. This aspect of therapeutic process has been studied mainly through the use of post-session questionnaires. These retrospective ratings utilize patients and therapists as participant observers of therapy to provide research data, and generally take the whole session as the temporal unit of observation. Greenberg and Pinsof (1986) present methods that rely on nonparticipant observation (chapters 2–8) as well as methods that draw upon participant observation (chapters 12–16), and a general overview of methodological issues is provided by Hill and Lambert (2004).

Main Process–Outcome Findings

Established Findings

A half century of accumulated research on psychotherapy has convincingly demonstrated that qualities of the therapeutic relationship, bond, or alliance robustly predict treatment outcomes – whether the relationship or alliance is observed from varied observational perspectives, and whether outcome is assessed by patients, therapists, clinical judges, and psychometric measures. Moreover, the issue of whether these relationship qualities produce outcome or merely reflect its ongoing attainment has apparently been resolved in favor of the former (Crits-Christoph et al., 2013). Global ratings of relationship quality are demonstrably linked to outcome from all observational perspectives. More specifically, the patient's personal investment, active collaboration, expressiveness, emotional responsiveness, and positive feelings toward the therapist seem particularly important (Bohart and Wade, 2013), as is the therapist's empathy and credibility (Norcross, 2011). This has led to a widespread view of the therapeutic bond or alliance as the most salient aspect of therapeutic process, and the 'common factor' that links therapists with patients to enable different types of psychotherapy to be more or less equivalent in effectiveness (e.g., Wampold, 2010).

With regard to therapeutic operations, some types of technical interventions (e.g., interpretation, experiential confrontation, and paradoxical intention), when skillfully focused on patients' life problems, have also been shown persuasively to be associated with positive outcomes (Orlinsky et al., 2004). In terms of participant self-relatedness, assessments of patient openness (vs defensiveness) have been very consistently associated with outcome. Likewise, patients' positive in-session impacts have been consistently found to predict positive treatment outcomes. However, in their recent overview of this area, Crits-Christoph et al. (2013) call for added methodological rigor, increasing controls of potentially confounding variables in order to establish which findings may reflect causal influences on outcome.

New Research Areas

Several new areas of study have emerged in recent years that expand the bounds of process research. Process studies traditionally focus on the interactions and experiences of patients and therapists within therapy sessions, as distinct from outcome studies that focus on patients' mental health status and emotional well-being in their lives outside of therapy. One new area of research explores the experiences that patients and therapists have regarding each other and their therapy outside of therapy in the time between sessions. Study of these inter-session experiences (IEs) extends the concept of therapeutic process into the traditional realm of outcome insofar as they shed light on how patients use what they learn in sessions to improve their outcome status. IEs are conscious, reportable events that presumably reflect a psychological process of internalization, which occurs largely outside the participants' awareness between sessions and enables episodic, relatively infrequent therapy sessions (typically 1 h per week) to become a continuous, cumulative experience for the participants (Orlinsky and Geller, 1993). Measurable indicators of that

psychological process are provided by the thoughts, feelings, memories, dreams, and fantasies that patients and therapists regularly report having between sessions about their therapy and each other. Patient IE reports have been related to the amount of personality disturbance, the therapeutic alliance and type of therapy, treatment outcome, and the internalization of therapists and therapy long after the termination of therapy. Therapist IE reports show how practitioners cope with difficulties encountered in their work with patients, and prepare for upcoming sessions. The value of research on IEs is twofold: showing how the psychological attributes and experiences of patients and therapists, in their lives outside of therapy, influence their actions and experiences during therapy (e.g., in the form 'transference' and 'countertransference' experiences); and showing how the events and experiences in therapy sessions in turn influence the subsequent psychological attributes and experiences of patients and therapists (e.g., how patients apply the new insights and skills acquired in sessions to problematic 'real-life' situations outside therapy).

A reciprocal extension of outcome evaluation into the traditional domain of process has occurred through research on the effects of feedback to therapists about patients' psychological progress or deterioration, and the utilization of this information by therapists to maintain or modify their practice (Lambert, 2010). Programs that monitor the patient's psychological state on a regular basis during the course of therapy were developed through advances in statistical analysis, which made it possible to project a patient's expected treatment response, combined with the use of computer technology to make real-time reports to therapists about their patients' progress or deterioration. This has proven especially helpful with patients who fail to meet expected benchmarks for improvement, or seem to be getting worse despite treatment, particularly if the therapists are provided with and use prompts about how to enhance the process (e.g., working to repair an alliance rupture).

Finally, a third new area of study uses recent technological developments to explore neurophysiologic concomitants and foundations of psychological change during the process of therapy (e.g., Carrig et al., 2009). These newly observable aspects of therapeutic process have shown early promise (e.g., Buchheim et al., 2012) and may gain more prominence in the future. They have already inspired several theoretical accounts of how behavioral and psychological changes may be understood in terms of neurobiological processes (e.g., Schore, 2003), but use of functional neuroimaging and electrophysiology is still largely uncharted territory and its value for studying therapy process remains to be demonstrated.

Process Research and Practice

Psychotherapy process research thus far has proven itself a scientifically successful field of inquiry. Initially, it had to overcome the skepticism and even hostility of some clinicians to having their work studied, as typified in a oft-quoted statement by Freud (1926/1959) that "the 'analytic situation' allows the presence of no third party …" and that "An unauthorized listener who hit upon a chance one of them would as a rule form no useful impression; he would be in danger of not understanding what was passing between the analyst and the patient …" (p. 185). Thus, in the earliest days, investigators were mainly concerned to demonstrate the feasibility of systematic and methodologically objective research on therapeutic process. Once that had been established (e.g., Rogers and Dymond, 1954), another 15 years or so were devoted primarily to devising reliable measures and rigorous methods of process research, during which time some therapists who had taken an interest in the field were disappointed by the methodological preoccupations of researchers and the paucity of clinically applicable results. However, the rate of research on process and process–outcome patterns increased steadily from about 1970 onward and, as the 1990s approached, a considerable body of well-replicated findings had been amassed, from which implications for therapeutic practice could begin to be drawn (e.g., Talley et al., 1994). Current pressures for accountability and quality assurance have forced therapists of all schools to become interested in outcome research, in order to demonstrate the effectiveness of their treatments (e.g., Goodheart et al., 2006). As a result of this pressure, clinical awareness of the relevance and applicability of process research has increased through a number of research-based contributions addressed to practitioners (e.g., Castonguay and Beutler, 2005; Duncan et al., 2010; Greenberg et al., 1993; Hubble et al., 1999; Lebow, 2006; Muran and Barber, 2010; Summers and Barber, 2010). Engaging practitioners has also been done through the development of 'practice research networks' (Parry et al., 2010), in which investigators and therapists collaborate to define research questions relevant to their clinical work, and collect and analyze data both for academic studies and for use to enhance practice. Further development of scientifically meaningful and clinically valuable process research may be anticipated through innovations like these.

Public Administration: Organizational Aspects

Abstract

This article considers 'Organizational Aspects' of Public Administration from its origins in the United Kingdom and United States of America prior to the 1850s, for the period from the 1970s to the present. It also considers the future of public administration.

Introduction

Public administration is the term traditionally used to define the formal arrangements under which public organizations serve a government, ostensibly in the public interest. The development of the public administration model dating from the mid-1800s to the early 1900s was influenced primarily by Weber's theory of bureaucracy, Northcote and Trevelyan's recommendations relating to the establishment of a professional civil service in Britain, and Woodrow Wilson's ideas in the United States for the separation of policy from administration (Hughes, 1994). Other managerial theories and concepts over the years have been relevant including Taylor's scientific management and Simon's rational decision-making. Since the 1980s, the traditional model of public administration has been largely rejected by governments in favor of a more focused managerialist model based on private-sector practice, within the context of a market-based economic model of public organization. In more recent years, there have been attempts to balance the economic focus with a renewed emphasis on public organization creating public value. This contribution will first examine the traditional model of public administration including the conceptual and theoretical bases and how this affected organizational aspects. Second, it will explore how and why there has been a paradigm shift from public administration to public management. Third, it will consider future trends.

Public administration is the term used to define the formal procedural and organizational arrangements under which public employees serve a government, by implementing and advising on policy, and managing resources. Organizational aspects refer to both the overall structures as well as the relationships that occur within public administrations. This could include: The organizations that make up a civil service, sometimes referred to as the machinery of government; internal organizational arrangements; and/or organizational behavior. Thus, organizational aspects can be studied in a broad sense or within several defined fields. This contribution covers organizational aspects, widely interpreted.

Beyond public administration as a discrete body of knowledge, organizational aspects can be examined through other theories and practices relating to, for example, political science, public policy, sociology, economics, and management. In this sense, each area of study has its own theories and concepts. Furthermore, each state has its own history, organizational form, and approach, although there are many universal, common elements, which have developed through the international transfer of ideas. New governments, formal review processes, focused research, and events have often stimulated notable change. Therefore, the area of public administration is a difficult area to research, and over the years studies have been largely descriptive rather than empirical.

For the purpose of this article, organizational aspects of public administration are examined as four phases of development and evolution, representing important paradigm shifts or prospective shifts. These are the premodern, modern, postmodern, and virtual/supranational phases. Critical issues relating to the theories, models, trends, and practices of organizational aspects of public administration during these times are explored.

Premodern Public Administration, Organizational Aspects (Pre-1850s)

The organizational aspects of public administration have been apparent from ancient times, through many civilizations, such as Greek, Roman, and Chinese dynasties, and have often been the subject of criticism and analysis. Indeed, the ancient Greek satirist and playwright Aristophanes was probably one of the earliest in the literate world to highlight the lack of accountability and fairness in relation to public office. The works of ancient philosophers, such as Plato and Aristotle, address pertinent issues of interest in this regard.

Military histories over many years from the ancient Greeks and Romans to Machiavelli, to Frederick the Great, and to Napoleon provide further insights into the evolution of organizational aspects of public administration. For example, in the 1700s, in the context of militarism and empire building, the Prussian leader, Frederick the and his successor, Frederic William III, structured an exemplary public administration. Furthermore, France's public administration, which had been evolving for decades through constitutional reform following the French Revolution of 1789, was organized on the basis of similarly functioning districts, or *départements*. In the late-1700s to early 1800s, Napoleon oversaw the central appointment of officials charged with the administrative responsibility for the *départements*. He also developed bodies, which undertook administrative review, and involved the separation of juridical and public administrative powers. The civil service was made up of a number of distinct corps, or bodies, supported by training schools.

In the context of royalty, an early patronage system of public administration developed in England, primarily, as a support function for the royal Anglo-Saxon courts. The later structuring of a distinct, centralized public administration was related to a concept of a parliamentary cabinet. Some senior government ministers had portfolio responsibilities and a small supporting staff. Separate departments eventually existed to provide administrative functions to the ministers in charge of the Treasury, the Exchequer, the Chancellery, and the State. Accountabilities of the ministers were divided, between the Parliament and the monarch. While ministers undertook many of the administrative duties because of a general lack of suitably qualified men [*sic*], a small, elite corps of public administrators was established with a resultant continuity of tenure from government to government. To a small extent, these public administrations served a legitimate purpose, but for the most part they existed to meet the needs and ends of the administrators themselves.

Some of the public administration ideas from Europe were also adopted in New World states. In the United States, in the context of a revolutionary federal constitution, which came after the War of Independence, their early patronage system was based on political connections, rather than royalty or class. Not surprisingly, these arrangements meant that the administrative organizations of government became highly corrupted, as Woodrow Wilson observed (1887). The dissatisfaction with this type of system and a promoted interest in reform processes led to the eventual development of professional public administrations in many states.

Modern Public Administration, Organizational Aspects (*1850s–1970s*)

Organizational aspects of public administration continued to evolve because of constitutional and parliamentary reform processes and, in some cases, shifts from royal courts to representative governments. The industrial revolution, the rise of capitalism, and the new bourgeoisie all contributed to pressures for professional civil services. Thus, in modern times, organizational aspects of public administration were based largely on the need for professionalism and often developed, further, because of administrative review.

In Britain, for example, the Northcote–Trevelyan Report (1853) recommended major changes in civil service recruitment and other processes. Fundamental to the changes was the establishment of a central Board of Public Administration, which eventually became a Civil Service Commission in 1870. The Board was responsible for the competitive recruitment, based on merit, of professional civil servants, and their appointment to departments; it was largely independent of government. From an organizational aspect, the idea of a central and independent agency of government responsible for recruitment and other personnel matters was instituted from that time. The best educated men [*sic*] with knowledge of history, classics, language, and mathematics were appointed to the service. Three classes of civil servant also applied: the elite administrative classes; clerical support classes; and the technical or professional classes.

In the United States, European and British theories and practices continued to influence reform of public administration, especially through the Civil Service (Pendleton) Act of 1883. However, there was a determination, as Woodrow Wilson (1887) notes, to 'Americanize' the system. The state was regarded as an instrument of social cooperation, and a more bureaucratic public administration structure was needed to manage the state. There was, however, always a fundamental rejection that the senior administration could perform in a nonpartisan way. This meant that there were dual streams of career civil servants and political appointees at the high levels of the civil service. Therefore, it was recognized that there was a blurred delineation between the political and public administration environments. High-level entry requirements were embedded into the career civil service, and a political education was favored as the main qualification. Taylor's (1912) theory of scientific management and related developments in the field were promoted as appropriate models of organization and work distribution.

Another major contributor to the evolution of ideas about public administration and organizational aspects was the German economist and sociologist, Max Weber. Weberian principles of bureaucracy have had a universal impact on the organizational aspects of public administration. These principles included the matching of fixed job responsibilities to defined, permanent positions; a hierarchy of official authority; the requirement for appointed, suitably qualified, and anonymous staff with continuity of tenure until retirement; recognition that high-level appointments bring social status; and entitlement for a salary and a retirement pension (Weber, 1946).

As an example of Weber's force, his ideas were evident as far away as Japan. Public administration and organizational aspects were based largely on German bureaucracy and Weberian principles, with other local attributes. This included the preferential acceptance of law graduates into the administrative elite stream, which has meant that the critical decision processes have been rule- and precedent bound. However, the developmental role of the state led to the dominance of certain elite governmental organizations, such as the Ministry of International Trade and Industry.

Furthermore, major events and trends, such as world wars and the growth of global trade, have impacted upon organizational aspects of modern public administration. Consequently, public sectors have increased in certain periods to address major reconstruction initiatives. Cycles of nationalization of certain industries have also impacted upon organizational aspects. Political history is important, too, and organizational change at a microlevel will usually occur when new governments are elected. Thus, there is a strong link between significant history and highly-dynamic organizational aspects of public administration.

Public administration has evolved as a distinct area of research and study in modern times. This is supported organizationally where, in concept, there is meant to be a clear separation of powers and responsibilities between political executives (governments); public administrations (civil or public services); and the juridical arena (the law and courts). There are obvious accountabilities between governments and public organizations, as well, given that there is usually a correlation between the portfolio responsibilities of members of the government and the way public administrative arrangements are determined. For example, members of a government are

allocated portfolio responsibilities pertinent to particular public policy fields, such as health, defense, or education. Typically, there is a defined public administration department dedicated to the implementation of government policy and/or service provision in the corresponding policy field.

Moreover, within public administrations, organization can take a number of forms. While categorization may vary from government to government, in general terms, five types of organization may be apparent. First, there are central agencies dedicated to coordinating and supporting government effort, responsible for areas such as financial and human resource management and management improvement. Second, there are departments charged with the responsibility for direct service provision to the public, across a broad range of policy fields. Third, there are government business enterprises (GBEs), which operate at a distance from government, in a more business-like way, usually providing some essential or commercial service. Fourth, there are the review and regulatory agencies, such as auditors-general, ombudsmen [*sic*], and anticorruption and whistle-blowing protection agencies. Fifth, there are the more peripheral boards and agencies, often semiautonomous entities that conduct other, sometimes more obscure, aspects of government business.

In general, these organizational aspects still apply, but the public administration bureaucratic paradigm, which endured for over 100 years were to a significant extent rejected by governments in postmodern times. By the 1960s, especially in Anglo-American polities, it was apparent that the modern paradigm of public administration, as it had evolved, was no longer serving governments, as intended. Public administrations were seen by critics and reviewers to be too big, too inefficient, and too powerful in comparison to governments. These criticisms were also linked to the perceived failure of Keynesian economic principles, which had underpinned governments' strategic policy decisions since the 1930s.

Postmodern Public Administration, Organizational Aspects (*1979–Present*)

It took until the late-1970s and early 1980s for fundamental changes to be implemented in a major paradigm shift toward a market-based model of public administration. Conservative political leaders Prime Minister Thatcher in Britain and President Reagan in the United States were the first politicians demonstrably to sustain such an approach, which led to early adoption in other Anglo-Saxon polities, and later around the globe. Similar earlier attempted changes had been evident in Latin America, where free-market concepts of the Chicago School were influential for a relatively short time. The market-based model, in varying forms, has been adopted in over 100 countries, worldwide, with some convergence of ideological thought between traditionally conflicting political parties. The market-based model supplanted communism in Eastern Europe in the late-1980s as a guiding ideology and led to revolutionary change in organizational form in other largely totalitarian states, such as the Peoples Republic of China.

Supranational governance structures, involving organizations such as the International Monetary Fund (IMF), the World Bank, the Organization for Economic Cooperation and Development (OECD), the Group of 7–8 (or more) leading trading nations, the World Trade Organization (WTO), and the European Union (EU), have all supported and promoted the market-based model. This may account for the active transfer and adoption processes in place from polity to polity. The EU, as the most comprehensive organizational form for supranational governance, operates with its own parliament and public administration system.

Several common themes based partly on public choice, and other less well-defined neoclassical economic theories of rational choice are characteristic of the market-based model. They all have implications for public administration and organizational aspects. First, for example, there is a move away from a mixed economy to a firm belief in markets as the primary and more efficient economic mechanism. To this end, deregulation relating to trade, finance, and monetary policies has taken place.

Second, if markets are to prevail, then the size of governments and their public sectors needs to be reduced. Included in the radical downsizing of public sectors is commercialization, and/or the privatization of GBEs where it is deemed inappropriate for governments to continue to operate in these areas. Major utilities and commercial businesses traditionally involving governments, in areas of activity such as telecommunications, power generation, distribution and transmission, water, banking, insurance, postal services, and airlines have been targeted.

Third, and most importantly, for the public sector, the strategic focus is on organizational efficiency, the creation of internal market-style competitive conditions, and the more purposive application of private-sector business techniques to public management. These changes have involved a shift from a focus on processes of administration and policy, however flawed, to organizational management. A business, or corporation, metaphor may be used to define organizational form. This change has been given various names in different polities; the most commonly adopted phrase is the New Public Management.

As a subset of public choice theory, principal–agent theory focuses on the relationships between governments and their top bureaucrats. In this interpretation, public bureaucrats are perceived to be budget-maximizing, self-interested agents, not trusted by governments. Therefore, governments need to develop executive structures where principal–agent theory can be applied directly so that governments can compel their administrative elite to act in the government's interests. The establishment of formal senior executive services, with formal performance agreements attached to incentives and fixed-term contracts may result.

Organizationally, the acceptance of the market-based model by governments has seen other major changes. These include, first, substantial machinery of government changes including the separation of policy, regulatory, commercial, and operational services and programs into discrete organizations. Second, the purchaser/provider split, where governments are the contract managers and service provision is contracted out. Third, more openly political appointments at the top of the public service are apparent in previously nonpartisan services. Frequently, this has involved the centralization of power away

from independent personnel bodies, which have been abolished. These senior executive managers are expected to support, publicly, governments' electability. In such circumstances, the possibility of ministers accepting responsibility for departmental managerial failure, within the construct of ministerial responsibility, considerably diminishes.

The rational choice logic, which underpins the market-based model, is open to question, given the presupposition of perfect markets and exchange processes. Such a conceptual framework is unrealistic for the political environment of public administration. Rewards for certain actions and behaviors of agents, required by the principals, can be achieved through both formal and informal power structures. This is an important organizational aspect of the market-based model, where parallel systems of exchange, reward, and relationships operate as a matter of course. While the formal systems may promote a constancy of action and process, the informal system can support implicitly institutionalized power–political relationships.

Whether the paradigm shift has resulted in better public administration and organizational aspects is still to be determined as the key economic indicators of performance, predicated within this new paradigm, suggest a mixed result. There has certainly been a shift from idiosyncratic or confined interpretations of public administration, relevant to particular nations, regions, or systems, to a more universal construct. Nevertheless, there are many variations on the market-based theme depending on governments in power and individual leaderships at any given time.

From an organizational aspect, one of the weaknesses of the market-based model is that it focuses strongly on economic issues and individualism, rather than on the collective responsibility of the state to its citizens. In this sense, social and related policy fields may be diminished in their importance. Some governments have attempted to redress this imbalance with more attention to social, environmental, and other imperatives, relating to the development of human and social capital. United Kingdom Prime Minister Tony Blair (1997–2007) coined the concept of New Labour, which was inspired by the advice and work of Anthony Giddens. The idea of New Labour was an attempt to balance market considerations with greater social concerns. To this end, in many polities there has been a shift toward an underpinning belief that governments and their public organizations are elected to create public value. Policies should, therefore, create a better balance between economic and social outcomes. Additionally, the continuing growth of supranational structures in terms of greater organizational form, and advances in information technology, now provide different challenges for governments.

Virtual and Supranational Public Administration, Public Administration (*Now and into the Future*)

These two developing areas of interest will undoubtedly continue to have major organizational impacts on public administration. With continuing extraordinary developments in information technology, governments are adding more virtual organizational forms to public administrations. For example, especially with customer service initiatives, knowledge management becomes increasingly important. Free information lines, supported by computer technology, provide coordinated details of government services. Similarly, virtual locations allow citizens to complete a range of government requirements, such as license renewals and the payment of bills. Many processes that involved members of communities attending government organizations in person now can be achieved more efficiently online. Comprehensive information can be obtained from government Internet Web sites, and civil servants can be contacted, more informally and directly, by e-mail. Many governments are now making extensive use of social media platforms such as Twitter and Facebook to inform and communicate with constituents. E-commerce, relating to procurement, contracting, and the lodging of documents may now also apply. Within governments, more virtual communication also takes place involving typed, aural, and visual media. Undoubtedly, this will continue to impact upon organizational aspects of public administration in the future, with a likely increase in virtual government. Organizational aspects of public administration will continue to expand through Web sites.

Second, the continuing development of supranational governance structures, in the context of globalization, has led to both cogent and conspiratorial debate in recent years about future organizational aspects of public administration. The Parliament of the EU as a structure challenging the individual sovereignty of national member governments is an example of how future organizational aspects may evolve as other trading coalitions consolidate their form. Governments in rapidly developing economies, such as the People's Republic of China, continue to make many changes to the organizational aspects of public administration as the shift toward a market economy continues to evolve. Responses to globalization, especially negative ones, however, prompt support for localism, which emphasizes the role of individual communities. The Global Financial Crisis of 2008 also has shown the vulnerability of the economically globalized world and how governments need to address crises through urgent administrative restructuring at such times.

With all these complex local and global pressures, it is likely that organizational aspects of public administration will continue to experience quite dramatic change over the decades of the twenty-first century. Whether the more traditional structures of agencies, departments, trading enterprises, and review bodies, with the complex relationships between key actors, will remain as the primary organizational aspects is difficult to predict. Even if they do remain, the more virtual aspects of public administration are expected to endure and grow to the point where there will be far more virtual public administration than there is in the second decade of the twenty-first century.

Public Broadcasting

Abstract

For much of the twentieth century, the dominant form of broadcasting globally was public service broadcasting. The essential premise of this form of broadcasting was that its role was to serve the public interest. To achieve this end, it was deemed crucial that the broadcaster should be free from commercial and political pressure, should seek to inform and educate the audience always with an eye to the quality of the programming on offer. This article offers a description of the principles of public service broadcasting, particularly as represented by the most famous and influential broadcasters, such as the BBC (British Broadcasting Corporation) .

The history of broadcasting, beginning in the early 1920s, has seen three main types or models of broadcasting organizations. One is the commercial model, in which advertising is used to provide revenues, with programs seen as vehicles for providing an audience to which products can be sold. A second model is one in which the broadcasting organization is funded by the state, usually so that the state can project its political message and thus influence the public. The third model is known in the United States as public broadcasting but in most of the rest of the world as public service broadcasting. The most famous and influential example of this model is the BBC. It is this model with which this article is concerned, particularly by defining it in ways that will allow the reader to see the fundamental difference between this and the other two models. The article examines the principles that were deemed to define the purpose and editorial policies of such organizations as the BBC. The article argues that the fundamental case that was, and is, made for public broadcasting is that absence of overt state and commercial pressure is the only way in which one can guarantee programming of quality and diversity, objectivity, and balance.

The General Concept and Background of Public Broadcasting

In a public system, television and radio producers acquire money to make programs. In a commercial system they make programs to acquire money. However simple, this little epithet articulates the divergence of basic principles, the different philosophical assumptions, on which broadcasting is built. History and experience fashioned inside public broadcasting a definable canon, a set of principles and practices which constitute the core theses around which the institution has been formed and which have guided its performance.

The particular institutional structures and forms of funding may vary from place to place, but public broadcasting is above all else an ambition, a belief that the sheer presence of broadcasting within all our lives can and must be used to nurture society, to provide the opportunity that society and its inhabitants can be better served than by systems which primarily seek consumers for advertisers or subjects for the state.

Some of the most powerful visions of the purpose of broadcasting emerged within unusual and trying circumstances. Consider, for instance, the cultural histories of the occupations of Germany and Japan in the late 1940s and the formulation of Allied policy for broadcasting in the rebuilding of those societies. Here was testament to the idea of broadcasting as primarily a social rather than an economic process, as something with moral, cultural, intellectual, and creative purposes and not just as a source of mild comment and moderate pleasure. The charters that established broadcasting in Japan and in Germany, by the Allied occupying powers, were replete with the public service ideal. If broadcasting was to comment, it should do so with a flourish. If it was to amuse, it should do so with elan. If it was to educate, it should do so with real professionalism. It was believed by the Allied leadership, including that of the United States, that the life of the mind of a society was far too precious and important to be left to what they took to be the vagaries of a commercial system or the oppressive force of state control.

It could be argued that such policies were creatures of the moment, as massive destruction demanded enormous reconstruction, of which communications would inevitably be part. But what was required was the restoration not just of highways, buildings, plants, but also of the shattered imaginative lives of whole populations. The architects of postwar Germany and Japan sensed correctly that healthy, diverse cultural institutions were a prerequisite to a functioning liberal democracy. Broadcasting was thus to be used as a key part of the cultural and social regeneration of those societies. In that lies the real clue to the nature and purpose of great public broadcasting: that it makes best sense when it represents a national and moral optimism within a society, when it suggests through the diversity and quality of its programs that societies be better than they are, better served, better amused, better informed, and, thus, better societies.

A period which is widely regarded within the advanced industrial societies as a high water mark of public service broadcasting is that of the BBC in the early 1960s. A key figure from those years was Sir Arthur, possibly the greatest of the chairmen of the BBC. In a pamphlet that he privately published in 1963 titled "What Is Broadcasting About?" he quoted from the report of the Pilkington Committee which had been set up by the British government to look into the future of broadcasting and published its report in 1962: "By its nature broadcasting must be in a constant and sensitive relationship with the moral condition of society." Sir Arthur felt that the moral establishment had failed modern society and that

broadcasting was a way in which that failure could be rectified. He added, quoting again from the Report, that it "is of cardinal importance that everyone in a position of responsibility should be ready to set himself or herself the duty of assuring, to those creative members of staff … that measure of freedom, independence and élan without which the arts do not flourish" (quoted in Tracey, 1983, p. 235).

That idea of providing a protective layer within which the imaginative spirit might create, lay at the heart of the BBC version of public service broadcasting which flourished in the postwar years and which constituted a model that other nations sought to emulate. Ian Jacob, Director-General of the BBC from 1952 to 1959, refined the notion. In 1958, in an internal document called 'Basic Propositions,' he described public service broadcasting as:

> … a compound of a system of control, an attitude of mind, and an aim, which if successfully achieved results in a service which cannot be given by any other means. The system of control is full independence, or the maximum degree of independence that Parliament will accord. The attitude of mind is an intelligent one capable of attracting to the service the highest quality of character and intellect. The aim is to give the best and the most comprehensive service of broadcasting to the public that is possible. The motive that underlies the whole operation is a vital factor; it must not be vitiated by political or commercial consideration.

This is one of the best attempts to capture in words a concept and view of broadcasting which continues to circulate in the world of cultural politics. Yet, even here the vision, the articulation, is limited. Jacob's words imply that we understand the nature of public service broadcasting not by defining it, but by recognizing its results, rather as one plots the presence of a hidden planet or a subatomic particle not by 'seeing' it, but by measuring the effects of its presence. The Pilkington Committee, on the future of British broadcasting, said as much in 1962 when it observed: "though its standards exist and are recognizable, broadcasting is more nearly an art than an exact science. It deals in tastes and values and is not precisely definable" (Home Office, 1962, p .13, para. 34).

One obvious characteristic of efforts to define public service broadcasting is the elegant vagueness that is studied and deliberate. In effect what is suggested is that one thing that has to be understood about defining public service broadcasting is that in any abstract sense one cannot; that whatever the definitional uncertainties, public service broadcasting can be experienced and recognized but never properly be captured by language. Inevitably, however, someone has to decide on what is 'good' and 'bad,' and that there is a guiding hand in making decisions as to what will and will not be produced, what has been referred to as 'the custodians, the caretakers' of culture. As traditionally understood by public broadcasters the whole idea of custodianship was totally unproblematic, as was understanding just who the custodians were, the characteristics they would possess, and the locations in which they would be found. Such presuppositions appeared only natural throughout the history of broadcasting because that history was embedded within a social order in which hierarchy was also assumed: hierarchies of social status and cultural judgment. And in a curious kind of way the point of hierarchy is to reproduce itself since the fundamental belief of the hierarchical system is, and has to be, that such arrangements have worth and merit. The plausibility of such a thesis becomes very much dependent on delivering evidence that attests to both worthiness and merit in such a way as to drown out the noise of any emergent countervailing thesis, most notably that this is an odiously elitist viewpoint.

A key justification for the custodial role in most societies where public service broadcasting was established was that since the radio frequency used for transmissions was a limited natural resource, someone had to ensure that its use served the public good, the whole community. The cultural geology of this decision had, however, a deeper level to it, based on nineteenth century assumptions about the ways in which the arts and humanities could elevate the human condition. In an essay on the formation of modern literary analysis, Steiner wrote that behind the study of literature in the nineteenth century lay:

> a kind of rational and moral optimism … a large hope, a great positivism … The study of literature was assumed to carry an almost necessary implication of moral force. It was thought self-evident that the teaching and reading of the great poets and prose writers would enrich not only taste or style but moral feeling: that it would cultivate human judgment and act against barbarism.
>
> Steiner, 1985, pp. 77–78

Reading this account one could quite properly substitute the word 'broadcasting' for 'literature' and have a powerful explanation of what the creation of the model of public service broadcasting was all about: a relocation of a nineteenth century humanistic dream of human betterment. The fear that drove that dream was of 'the mob,' the pervasive belief among cultural, religious, and political elites that there was indeed a dark side to the human soul that was, when let loose, dangerous and devastating to the flesh as well as the spirit. Whatever the apparent elitism who is to say that they were wrong nestling, as they did, between the first great war and a looming second? There remained, however, a residual faith, tied to the whole condition of the Enlightenment, humanism, and belief in progress, that popular culture need not be debauched but could in fact transcend itself. Consider this key passage from the Pilkington Report:

> Television does not, and cannot, merely reflect the moral standards of society. It must affect them, either by changing or by reinforcing them…Because the range of experience is not finite but constantly growing, and because the growing points are usually most significant, it is on these that challenges to existing assumptions and beliefs are made, where the claims to new knowledge and new awareness are stated. If our society is to respond to the challenges and judge the claims, they must be put before it. All broadcasting, and television especially, must be ready and anxious to experiment, to show the new and unusual, to give a hearing to dissent. Here, broadcasting must be most willing to make mistakes; for if it does not, it will make no discoveries.
>
> Home Office, 1962, pp. 19–20, paras. 50–53

The suggestion here is not that public broadcasters are all hoping and dreaming that their programs will transform

people from cultural and intellectual slobs into something of which one can more readily approve, but rather that objectively some such argument must be the public broadcaster's last line of defense. The language is of standards, quality, excellence, and range. The logic is of social enrichment, that in however indefinable a manner this society is in, it is 'better' for having programs produced from within the framework of those social arguments termed public service broadcasting, compared to those programs produced within an environment in which commerce or politics prevail.

One cannot, however, escape the charge that those sentiments rest on a set of ill-explored assumptions about the sociological organization of modern culture. How are we better? What are the mechanics? And, vitally, where is the evidence? Indeed, what would such evidence even look like?

The Public Service Idea: Eight Principles

What then are the definable principles of public service broadcasting? Eight principles were identified by the London based Broadcasting Research Unit (of which the author was the director) and are summarized in the following sections.

Universality of Availability

Public broadcasting has historically sought to ensure that its signals are available to all, that no one should be disenfranchised by distance or by accident of geography. The imperative that guides this principle is not that of maximizing customers in a market but of serving citizens in a democracy, that if one defines one's audience as the citizens of a country, then logically one has to reach them all. To a remarkable extent in country after country this principle has been made real.

Universality of Appeal

Public broadcasting seeks to provide programs that cater to the many different tastes and interests that constitute a society's life. The public broadcasting community understands that each of us, at different moments, is part of a majority and a minority. In seeking to provide programs for a wide range of tastes and interests, public broadcasting does so with an eye cocked to the need to ensure that whether the program is pitched at the many or the few it is done so with real quality. Public broadcasting does not expect that it can please all the people all of the time – indeed it sees in that approach precisely the kind of populism that nurtures cultural mediocrity, as quality is sacrificed on the altar of maximizing the audience size.

It is an important element of this principle that public broadcasting serves not only tastes and interests that are readily apparent, but also those that are dormant and latent – that may be part of the potential we all possess but that circumstance may not have allowed us to develop.

Provision for Minorities, Especially Those Disadvantaged by Physical or Social Circumstances

It is commonplace to characterize the medium of television as essentially serving 'the mass.' Certainly, public broadcasting understands the vast capability of one medium to reach enormous numbers of people. It sets its face, however, against the logic of commercial systems to see people as no more than statistics in skins, with a definable value captured in the most desirable rates, demographic buys, and cost per thousand. As suggested in the second principle, public broadcasting views the public as a rich tapestry of tastes and interests, each of which, insofar as possible, should be served.

In particular, it recognizes that there are whole subcultures of minority social experiences crying out for attention. People of different color, language groups, and religious preferences all have vital needs for expression in the political and social discourse of the nation. Public broadcasting is dedicated to a dual role here – on the one hand to give access to such groups, to provide them with the opportunities to speak to one another, and to voice the issues as they see them, and on the other to provide coverage of their histories, interests, and concerns for public at large.

Serving the Public Sphere

Some television programs are successful because they get a fair-sized audience, make some money, and sometimes even exemplify the craft of popular television. Other programs are successful because they reach out and touch a small, particular, but powerful audience. Some programs are successful because the craft of the program maker is used to speak to us all. They touch us, move us, make us laugh and cry, and cheer. They speak to us because they speak for us. Like all great art, they help us make sense out of life, to see and understand things with a fresh eye, and give us a burning sense of the collective, of belonging to the nation-as-community. It is an increasingly vital principle of the work of public broadcasting that it recognizes its special relationship to a sense of national identity and broad community. Any nation is a patchwork of localities and regions, but it also is a nation, heterogeneous and homogeneous to a remarkable degree at one and the same time. Public broadcasting's very nature is then to nurture the public sphere as a means of serving the public good. It understands that while within civil society individuals pursue their own private self-interests, it is within the public sphere that they function as citizens. It is a fundamental principle then that public broadcasting must motivate the viewers as citizens possessing duties as well as rights, rather than as individual consumers possessing wallets and credit cards.

A Commitment to the Education of the Public

The most outstanding example of public broadcasting's commitment to the audience-as-citizen is the long-time provision in almost all systems of educational programming at every level. Public broadcasting knows that political and social literacy, as well as of course literal literacy, is an essential prerequisite to the healthy working of a democratic order. Above all else, the commitment to this principle requires that it treats its audience as mature, rational beings capable of learning and growing in many ways. Thus, much of public broadcasting has retained its commitment to institutional services. Daytime school broadcasting and formal learning services of all kinds continue to play a role in most national services.

Independence from Vested Interests

It is a simple but key principle of public broadcasting that its programs can best serve the public with excellence and diversity when they are produced from within a structure of independence. Programs funded by advertising necessarily have their character influenced in some shape or form by the demand to maximize the garnering of consumers. Programs directly funded by the government, and with no intervening structural heat shield, inevitably tend to utter the tones of their master's voice.

The whole history of public broadcasting has been dominated by the idea that it can best serve the nation when it remains distanced from any particular commitment to any particular power structure inside the nation. Of particular importance to this principle is the ability of public broadcasting to support a cadre of independent-minded program makers, who are thus well able to speak with authentic tones and to offer that singularity of vision allied to creativity and passion that has traditionally produced some of public television's finest moments. It follows that the political and economic architecture of this principle is such as to support the making of programs that are good in their own terms, whatever their intended audience. In the making of programs for public broadcasting, there should be no ulterior purpose or motives. It is axiomatic to this principle that the funding of public broadcasting should be such, in total amount and in the absence of any strings attached, as to encourage rather than negate the independence enjoyed.

Encouraging Competition in Good Programming Rather than Competition for Numbers

This principle is central to public service broadcasting and essentially involves a commitment to making programs which, whatever their intended audience, are of high quality. The overwhelming brunt of the evidence leads to the conclusion that the most important aspect of such structuring relates to the forms of finance. Where commercial sources of revenue are dominant, or even present, or where there is direct subvention from government, the program maker's eye is almost inevitably diverted away from what should be the main focus, the inherent quality of the program he or she is making.

The Rules of Broadcasting Should Liberate Rather than Restrict the Program Maker

While all broadcasting will inevitably be governed by certain prescriptions – 'educate,' 'inform,' 'entertain,' 'balance,' and 'fairness' – and certain broadly drawn restrictions – obscenity and national security – the essence of the legislative foundation by which it is empowered should sustain a liberal function for the program maker. The legislation should create secure living space, arena for action, for broadcasters with all kinds of interests in possible programs and possible varieties of audience, rather than leaving the field to those who are interested chiefly in delivering maximum audiences most of the time. The legislation should also ensure that the higher echelons of broadcasting contain individuals who understand its potential and who themselves care for the importance of the creative work of their staff. Part of that understanding would be the need for experiment and innovation in broadcasting, the need to provide a focus for a society's quarrel with itself and the recognition that mistakes will be made but as such may signify the health of the system.

Perhaps above all else, such leadership should be helped to understand that experiment, innovation, quarrel, and mistake are likely to come from the younger program maker, without whom the system is in danger of institutional arteriosclerosis.

Public Service Broadcasting in the Twenty-First Century

In recent years public broadcasting everywhere has faced increasing challenges from a number of quarters. The digital revolution and the rise of the multichannel world of cable and satellite television has posed serious competitive pressure on national public broadcasters. This is because not only is there greater competition for the audience, but also because public broadcasters have felt the need to offer their programming not only in the traditional way, but also to develop new platforms and new programming product to meet the digital challenge. There has, however, in recent years been another, more subtle, but none the less important, change in what is expected of them. In almost every country governments have developed economic policies which encourage the play of market forces in almost every facet of life, and culture and broadcasting are no exception. The increase in competition has already been referenced, but public broadcasters are increasingly being asked to justify their value to the society not in some loosely defined manner, but in what can only be called econometric ways. A key concept which has emerged and, indeed, which has been incorporated into the official policy of such broadcasters as the BBC, is that of 'Public Value.' The term has been defined by the man most closely associated with it, Mark Moore, in this way: "public value is that which the public values." This implies that increasingly the basic model that determines the ways in which public broadcasters will function has moved from the classic public service/culture model, to one that more closely resembles the market model. Some observers have interpreted this as suggesting not just a different role for public broadcasting, but also that there is now a very serious question mark over the whole future of public broadcasting in the very different world of the twenty-first century.

Public Bureaucracies

Abstract

Throughout history public bureaucracies have served as a source of continuity and stability in the life of the State. This role has sometimes led to their becoming a significant obstacle to innovation in government policies. More recently, however, these bureaucracies have also become useful agents of change in many societies. The power that bureaucrats exercise comes mainly from the expertise they command both as individuals and when linked together in organizations. This power has come under increasing challenge in the industrialized democracies. Other institutions – governmental and nongovernmental – have begun to acquire their own expertise, and public bureaucracies are less able to cloak their operations in secrecy. Moreover, many public agencies that formerly performed regulatory or service delivery functions have been abolished, and private or quasi-public organizations have begun to perform tasks that were once within the exclusive preserve of government agencies. By the end of the twentieth century it had become clear that public bureaucracy was not the growth industry it had appeared to be in the aftermath of World War II, 50 years earlier.

The power that bureaucrats exercise comes mainly from the expertise they command both as individuals and when linked together in organizations. This power has come under increasing challenge in the industrialized democracies. Other institutions – governmental and nongovernmental – have begun to acquire their own expertise, and public bureaucracies are less able to cloak their operations in secrecy. Moreover, many public agencies that formerly performed regulatory or service delivery functions have been abolished, and private or quasi-public organizations have begun to perform tasks that were once within the exclusive preserve of government agencies. By the end of the twentieth century, it had become clear that public bureaucracy was not the growth industry it had appeared to be in the aftermath of World War II, 50 years earlier.

Bureaucracy: The Permanent Government

Although perhaps the least venerable, public bureaucracies rank among the oldest of all existing government institutions. Such bureaucracies played a central and continuing role in the operation of two of the largest and the most effective of the empires that emerged in the early stages of human history, the Chinese and the Egyptian, as they did in the imperial systems of Rome and Byzantium. Each of these was a political system that endured for centuries.

As history evolved and as nation-states emerged as the dominant form of political community in Western society, public bureaucracies were still able to demonstrate as formidable a capacity for holding on to power as their ancient forbears. Even when other political institutions, such as elected executives and legislatures, began to emerge as new centers of government authority, these public bureaucracies still managed to maintain a leading position in crafting and carrying out state programs and decisions.

This continuity in the exercise of power enabled public bureaucracies to be a source of stability in the life of a nation even when fundamental changes were taking place in the nature of the regime they served. Alexis De Tocqueville has given us a memorable description of bureaucratic organizations serving in this way amidst the turbulence of French politics at the end of the eighteenth century: "For though in each successive revolution the administration was, so to speak, decapitated, its body survived intact and active. The same duties were performed by the same civil servants…These men administered the country or rendered justice in the name of the King, then in that of the Republic, thereafter in the Emperor's" (De Tocqueville, 1955).

Bureaucracy and Change

Since De Tocqueville wrote, the role that public bureaucracies can play as a stabilizing force in societies beset by a time of troubles has sometimes been seen in a less favorable light. It is argued, for example, that their durability as government institutions has enabled bureaucracies to function as an obstacle to change in the social order, long after it has become clear that such change is urgently needed. During the twentieth century, some bureaucracies, especially in the military sector, have played this kind of obstructive role in the emerging nations of Africa and Asia. In its most extreme form, resistance to change on the part of a public bureaucracy may even lead a government agency to sabotage programs placed under its control that it opposes.

Bureaucracies as Change Agents

In the modern world, however, it is also possible to find public bureaucracies that serve not as barriers to innovation but as

agents of change in their own societies. When Social Democratic political parties came to power in Europe after World War II, it was widely anticipated that the reforms they intended would be undercut by the conservative bureaucracies in their own country that would be responsible for putting these programs into effect. This kind of sabotage did not in fact occur. Such bureaucracies carried out the changes proposed by the Labour Party when it took control over the British government after the parliamentary elections of 1945 with the same diligence they had shown when administering the programs of the Conservative governments under which they had previously served.

Moreover, one of the enduring legacies of that great period of social and economic reform in the USA in the 1930s, which came to be known as the New Deal, was the creation of new bureaucratic organizations such as the Rural Electrification Administration (REA) and the Tennessee Valley Authority (TVA) that were designed to serve neglected sectors of the American population. In the 1960s a similar reform movement gave birth to agencies at all levels of government in the USA that were authorized to protect women and minority groups from discrimination in employment and other spheres of everyday life. Of course, even when a bureaucracy is created to serve as an agent of change, it can still find itself under attack from its own supporters on the grounds that it is insufficiently zealous in pursuing this objective. As a result, the stereotype of bureaucracy as an obstacle to change tends to endure, even in settings where an organization is breaking new ground.

The effort to use public bureaucracies as instruments of social reform is the product of a general movement toward democracy that has taken place throughout the Western world. As this has occurred, victory in regularly scheduled elections has become the chief source of empowerment, and the political parties competing in such electoral contests have every reason to see public bureaucracies as vehicles for promoting policy changes or carrying on programs that will ultimately provide the political support necessary to win or maintain control of the government. This convergence of interest between party and bureaucracy has energized the effort in modern democratic societies to use bureaucratic institutions as instruments for breaking with the past rather than preserving it.

Bureaucratic Expertise

Throughout history the fundamental source from which public bureaucracies derive their power is the possession of a body of knowledge or skill indispensable to the successful performance of the government in which they operate. In many cases, especially during the early stages in their historical development, these organizations held a monopoly of such expertise. In addition to the influence it gave them within the councils of government, it enabled them to win a certain measure of deference within the community at large. To be sure, this deference was usually coupled with hostility, since ordinary citizens commonly resent the power exercised by bureaucrats in democratic as well as authoritarian societies. Such antagonism toward bureaucracies is perhaps the chief way in which these disparate systems of government continue to resemble one another in the modern world.

Over the course of modern history societies have differed in their willingness to allow expertise to become the signature characteristic of their public bureaucracies. The UK, modeling itself after the example of ancient China, pioneered in this respect, and various segments of the British Empire followed this example even after they won independence. In the more egalitarian culture of the USA, proposals to establish such a Mandarin-style bureaucracy met with strong initial resistance in the nineteenth century as betrayal of the country's democratic traditions. A similar outcry can still be triggered today in US politics by proposals that the country create an institutional counterpart to France's '*Ecole Nationale d'Administration*,' a school for the training of the French administrative elite.

Competition among Experts

One development that has greatly diminished the advantage public bureaucracies derive from their command over bodies of expertise in specialized areas of government policy has been the gradual migration of such expertise to other institutions of government. In the USA, for example, Presidents now have a large number of experts of their own clustered in various units within the Executive Office of the President. While Prime Ministers and Cabinet members in the parliamentary systems that prevail elsewhere in democratic societies do not have similar access to such organized cadres of experts, they are often able to turn elsewhere to satisfy their need for expert assistance.

The Rise of Think-Tanks

Another important source of expertise widely available to elected officials today lies within the private sector in the form of private research organizations known as 'think-tanks' that have emerged and begun to focus on current issues of government policy in the Western democracies. The research findings of these organizations sometimes attract almost as much, if not more, public attention than the reports emanating from the public bureaucracies whose work they monitor. In earlier days these think-tanks tended to provide intellectual support for programs and policies that led to an expansion in the size and power of public bureaucracies, especially in the areas of the social services and economic regulation. More recently, however, think-tanks with a conservative orientation have begun to emerge, and they have provided intellectual ammunition for groups critical of public bureaucracies and the programs and policies these organizations pursue.

Bureaucratic Secrecy and Open Government

The emergence and expansion of new forms of mass communication has tended to make public bureaucracies increasingly vulnerable to scrutiny and criticism from institutions and groups outside the government. Pressure from such media organizations has been chiefly responsible for the enactment in a number of modern societies of 'freedom of information' statutes which require public bureaucracies to provide information in their files to private citizens or groups upon request, except for certain specified categories of data. Max Weber long ago saw the secrecy in which the public bureaucracies of his day

normally operated as a major source of the power they exercised. As a study edited by Itzhak Galnoor has shown, the scope of such secrecy has been greatly narrowed in both Europe and the USA today.

Alternatives to Public Bureaucracies

Critics of the role of public bureaucracies in government, or of the programs they administer, have long argued that they are in fact immortal institutions, which, once established, are impossible to terminate. Certainly it is true that such bureaucracies are tenacious organizations, sinking deep roots into the fabric of the societies they serve.

Still, recent developments in modern societies make it abundantly clear that public bureaucracies are far from immortal. During the past two decades a wide variety of regulatory agencies have been put to death in both the USA and Europe, casualties of a bi-partisan consensus that they mainly serve not the public but the interests of the industries they regulate. Public bureaucracies have also been victims of the growing belief that private ownership is more efficient than state operation. A striking example of this trend occurred in Canada in 1996, when Parliament transferred the vital task of carrying on the country's air traffic control system from the government's transport department to a nonprofit firm created by the legislature.

Along with these developments, there has been a continuing expansion in both Europe and the USA of organizations in the nonprofit sector that administer programs that were once thought to lie within the exclusive domain of government. These nongovernmental agencies, or 'semi-public' bureaucracies as they might be called, supplement rather than supplant the work of public bureaucracies in such areas as health, welfare, and education, and much of their revenue actually comes from the government itself. One such organization in the international sphere – Medecins Sans Frontieres – received the Nobel prize for Peace in 1999 for its work in providing medical care and moral support for population groups in distress around the world.

Public Choice Economics

Abstract

Public choice is the application of economic methods and behavioral assumptions to nonmarket collective choice institutions. There are six major questions that public choice has focused on: collective action, controlling Leviathan, delegation, democratic coherence, information problems, and rent-seeking. Public choice has important implications for institutional design, particularly under the assumption that political actors may be motivated by interests other than the public interest. Public choice has given rise to important areas of study in empirical behavioral economics, including experimental economics, and to the study of common pool resource management institutions.

Introduction

The school of social science called 'public choice' is not sharply identified as an approach or a subject matter, but includes a variety of types of research. Nonetheless, as a general matter, public choice can be defined as the application of economic methods and behavioral assumptions to collective nonmarket institutions.

The foundational assumptions used are often methodological individualism, constrained utility maximization for all human agents, high transactions costs, and incomplete and/or asymmetric information. The focus of study is on institutions, formal or informal, that aggregate information or preferences, and that foster (or thwart) cooperative action intended to capture collective benefits. James Buchanan, 1986 Nobel Laureate and one of the founders of the public choice movement, has argued in several publications (Buchanan and Tullock, 1962; Buchanan, 1975) that public choice is a theory of exchange-based government by self-interested individuals. More briefly still, Buchanan (1999) simply said that public choice is 'politics without romance,' but he was careful to define 'politics' as a means of exchange, or achieving cooperative outcomes and mutual gains.

Six Key Problems

There are six key problems that public choice theory (PCT) has focused on. These six are listed below, along with the scholar or scholars who made the most important contributions in describing the problem:

- Collective action (Olson)
- Controlling Leviathan (Buchanan)
- Delegation (Niskanen and McNollGast)
- Democratic coherence (Arrow, Black, and McKelvey)
- Information problems (Coase, Downs, Hayek, and Tullock)
- Rent-seeking (Krueger and Tullock)

Each of these fundamental problems has important connections to other work in economics, law, or political science, but the particular contributions of PCT are unique and identifiable. (For an extended commentary on this work, and other aspects of the development and impact of PCT, see Mueller, 2003; Rowley and Schneider, 2003.) That is, research on these six problems is not necessarily a contribution to PCT, but PCT is largely composed on work on these questions.

Collective Action

The classical theories of interest groups (Bentley, 1908; Truman, 1951) conceived of group preference intensity as an anodyne counterweight to simple majorities. But there was an underlying assumption that intensity of preference measured total costs and benefits, defined somehow in interpersonally comparable utility units or in money. This meant that outcomes of interest group contests were more likely to track the optimal outcomes for the society. The reason is that interest groups were conceived as vectors of force (intensity multiplied by group size) allowing a comparison of policy choices, weighted by utilities.

This optimistic view of government action was forever shattered by the publication of Mancur Olson's *Logic of Collective Action* (1962). Olson's argument had two steps. First, 'groups' are different from collections of citizens. To form a group, citizens need some form of organization, and means of acting collectively, to focus their political power. Second, not all collections of citizens are equally likely to form an effective group. There are three factors that substantially determine the success of latent collections of citizens in engaging in effective collective action. These are (1) group size; (2) individual benefits and costs of participation; and (3) the capacity to provide selective incentives for group participation.

Olson pointed out that small groups, because they face lower costs of communicating and negotiating, and are more likely to have personal connections, are more likely to form effective political units. Large groups may fail to form effective units, precisely because their large size and anonymity allow individuals to 'free ride,' and fail to contribute.

The free rider problem is exacerbated if benefits are dispersed. It is easy to imagine that a group stands to benefit $1000 if it can raise $200 to organize. If the group contains four members, each of whom expects $250 in benefits, it is likely one member would pay the entire $200 cost, if necessary, because there is still a net benefit of $50 to that individual. But if there are 10 members of the group, each of whom expects a benefit of $100, no one will pay $200. If the group fails to organize, there is no chance of acquiring the benefit.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71071-3

Olson's conclusion was not that groups fail to organize. Rather, he concluded that successful groups managed to communicate and solve the free rider problem either through social capital or through the provision of direct benefits to participation that might be quite orthogonal to the group's public purpose. He called these orthogonal benefits 'selective incentives.' One might not be interested in a group's political agenda, but might be willing to contribute if the group can provide access to a magazine with pictures he or she enjoys (guns for the National Rifle Association, cute owls and seals for the Sierra Club). Or, one might contribute to public radio because he or she really wants the mug and the tote bag.

Controlling Leviathan

The symbol of the journal, *Constitutional Political Economy*, cofounded by James Buchanan, is a struggling Odysseus bound to the mast, with the Sirens in the background. The key problem Buchanan has been concerned about is reaching and enforcing agreements among groups of people who recognize that all have substantial incentives to cheat on the agreement once it is reached. If the enforcement powers of the state that the group constitutes are too weak, then cheating will be immanent. But if the enforcement powers are too strong, or cannot be constrained to the domain and procedures outlined in the agreement, then the Leviathan itself will cheat. Hobbes (1651/1990) despaired when confronted with this problem, and concluded a bad autocrat is better than anarchy. Buchanan argues that there is another option: constitutional contractarianism.

PCT (as Buchanan and Tullock, 1962, argued) conceives of government, for the most part, as an enforcement mechanism for capturing gains from exchange, based on voluntary agreements among groups of citizens. Government's function is to specialize in the production of public goods, controlling for externalities, and adjudicating disputes over property rights. Consequently, there are two stages of interaction. The first is the selection of rules – including rules for changing the rules – for which unanimity or something close to it is desirable. After rules are selected, participants choose actual strategies and actions, and outcomes are the product of the interactions of those strategies, under the rules. No one can choose outcomes, alone.

The problem is that constitutions may not be able to restrict the use of coercion to the domain everyone agreed on (Buchanan, 1975). Further, even a properly constrained, well-functioning government will sometimes engage in actions that look very much like coercion, because majorities choose policies and people who violate the legislated rules are punished. But the 'coercion,' in this view, is voluntary, because participants consented to the rules. As Brennan and Buchanan (1985) note, the problem of enforcement may be less severe than what a pure self-interest model might predict, because if the rules are consistent, and fairly enforced, citizens may internalize the rules as being 'the right thing to do,' creating moral sanctions against rule violation.

This suggests two important roles for limiting Leviathan. The first is that a set of choices and actions is set aside for individual autonomy, beyond the power of majorities to dictate or interfere. In the United States, this takes the form of a 'Bill of Rights,' limiting the power of government. The second is that rule of law and equal protection are absolute requirements for the application of legitimate coercion. A group of people might decide, for example, to impose taxes on themselves to finance the provision of a public good they all desire (North and Weingast, 1989). But the tax rate could not discriminate, and all citizens would have to be treated equally, and have recourse to due process for appealing decisions of the taxing authority.

Delegation

To 'delegate' is to entrust obligations to others, at the same time giving those others the powers to fulfill the obligations. In government systems, the policy/administration dichotomy – or any 'separation of powers' structure – requires an act of delegation. There are two large literatures that come together in the study of delegation in PCT. The older literature is on bureaucracy; the second, newer literature addresses the principal-agent problem.

Max Weber wrote that the bureaucracy represented an improvement over previous systems of organization. Ludwig von Mises (1944) and later William Niskanen (1971) were less optimistic about delegation of powers to bureaucracy, because bureaucrats are people, too. A 'public interest' theory of the institution of government is plausible enough, because government is established to secure and enforce the terms of the collective contract. But it is not plausible to assume that, just because bureaucracies are established to advance the public interest, the actual men and women who work in bureaucracies have the public interest as their personal goal. Consequently, they are no less likely than any other kind of citizen to try to manipulate pay, work conditions, and information to their advantage. The problem is that bureaucracy is uniquely insulated from normal economic incentives for efficiency. This is true partly because of the structure of bureaucracy, focusing on rules and procedures rather than outcomes or production.

But this is not a flaw of bureaucracy itself. Rather, the reliance on government provision in a territorially extensive state requires the use of bureaucracy. There is actually no alternative form of organization. The question, posed pointedly by Niskanen, is whether this means that the selection of government provision is correct in the first place. Niskanen noted that bureaucrats can be expected to try to expand their budgets, motivated either by simple self-interest or a public-spirited honest belief that their agency needs to increase its level of service provision and transfer payments. Given the ability of top agency officials to disguise their true costs and manipulate budgets, this means that elected officials charged with oversight are unlikely to be able to have enough information to control agency actions effectively.

Of course, Niskanen goes on to point out that it may not matter much anyway. The official who selects a position on the oversight committee for an agency is likely to have a personal or electoral interest in that agency's activity and budget. Consequently, if oversight officials are themselves relatively high demanders of the agency's services, the 'oversight' process is, in Niskanen's phrase, a 'stylized farce,' with oversight committees' main job being to check to see if the agency has correctly estimated the maximum budget that can pass the entire legislature on final passage.

The second major approach in PCT, the principal-agent literature, considers some of the same questions, but looks at the problem through the lens of contract design and – in the case of bureaucracy at least – the promulgation of administrative procedures and law as a means of eliciting the desired performance in bureaucratic agencies. One of the first articles to take this problem seriously was Romer and Rosenthal (1978), who argued that the problem of control in delegation rests on three institutional variables: agenda control, the possession of the *de jure* or *de facto* veto powers, and the reversion point, or outside option in negotiations. Barro (1973) and Ferejohn (1986) made important contributions to the idea of delegation of authority from voters to elected officials.

Some of the most important work in principal-agent delegation in PCT is by the composite author whimsically referred to as 'McNollGast,' or McCubbins, Noll, and Weingast. The precursors to this work include Weingast and Moran (1983), Weingast (1984), and McCubbins and Schwartz (1984). This led to McCubbins et al. (1987, 1989), which, along with Miller (1992) are the major summary of the administrative and management procedures problem in principal-agent PCT.

With Miller (1992), the literature had connected back to the origins, in Niskanen (1971), of a general model of organizational structure. Though Niskanen had written about bureaucracy and 'representative government,' his original inspirations to think about the bureaucratic form had come while he was employed as chief economist at Ford Motor Company, and witnessed there also the difference between 'markets and hierarchy,' as Miller put it. The fact is the market processes and bureaucratic processes are substitutes only at the margin. In most instances, it is clear what organizational form is required, if the activity is to be carried out efficiently.

Democratic Coherence

Groups of people who all agree, unanimously, have no problem deciding things. Literally any responsive (i.e., based on voter preference) decision rule would yield the same, correct outcome. Democracy matters most when there is disagreement. The difficulty is that when there is disagreement there is a chance of political incoherence, because democratic procedures are indeterminate.

This possibility was originally recognized long ago (McLean and London, 1990, 1992). But the problem was rediscovered, for majority rule, by Black and Newing (1951) and most importantly Black (1958), one of the founding documents of the public choice movement. It turns out that if there are three choices, three choosers, and complex disagreement, then majority rule may be radically indeterminate. Black (1958), to his credit, investigated whether this problem had been investigated before, and uncovered contributions by Condorcet and Borda whose implications had not been recognized – not even by Condorcet and Borda themselves!

A parallel development (Arrow, (1951/1963)) connected to this result by showing that the indeterminacy was not simply a property of majority rule, but of any aggregation mechanism. Arrow showed that, making only apparently innocuous assumptions about the features of the preference aggregation rule, or (in the case of welfare economics) the social welfare function, there is no mechanism other than dictatorship that always produces a complete and transitive aggregate ordering over outcomes. To the extent that dictatorship is ruled out by normative concerns for citizen participation and autonomy, then, there is no consistently ethically defensible solution to the aggregation problem.

And yet groups have to choose. The public choice conclusion is that what is required is humility; the outcomes selected by voting processes, ranging from elections to simple democratic choices over policy, are the results of a decision process, and nothing more. A different decision process would almost certainly have yielded a different outcome, even if exactly the same preferences were being 'represented.' Thus, since there is no unique mapping from preferences to outcomes, institutions of choice are central problems for a polity. As William Riker (1982) put it:

> We should never take the results of any method always to be a fair and true amalgamation of voters' judgments. Doubtless the results often are fair and true; but unfortunately, we almost never know whether they are or not. Consequently, we should not generally assume that the methods produce true and fair amalgamations. We should think of the methods, I believe, simply as convenient ways of doing business, useful but flawed. This gives them all a place in the world, but it makes none of them sacrosanct. (p. 113)

This work has led to an accumulation in the understanding of the nature of political power in a democracy. It is now known that political power lies at the 'center' of the distribution of preferences effectively enfranchised by the institutions of the society (Downs, 1957; Black, 1958). Majority rule has substantial power, from an ethical perspective, as a normatively defensible decision rule (May, 1952). But it turns out the sufficient conditions for the existence of equilibrium in majority rule decision (Plott, 1967) still leave the question of the necessary conditions for equilibrium dependent on a variety of assumptions about information, institutions, agenda control, and voter sophistication (McKelvey, 1976; Hinich, 1977; Enelow and Hinich, 1983; McKelvey and Schofield, 1987).

There are two separate problems of democratic coherence. One is the problem of agenda control and manipulation. The power to choose institutions can be tantamount to dictatorship, or at best give the agenda controller disproportionate power inconsistent with a democratic 'one person, one vote' ethic (McKelvey, 1976; Miller, 1995). Of course, disputes over outcomes can metastasize into disputes over institutions of choice, as Riker (1980) famously pointed out. The second problem is the arbitrary or 'imposed' nature of institutions. Having one institution for choosing, rather than another, can have a striking impact on outcomes, just for reasons of historical accident or path dependence (Shepsle, 1979, 1991; North, 1981; Baron and Ferejohn, 1989). Since institutions are costly to change, and since the translation of preferences into outcomes is so uncertain, collective choices may be locked into suboptimal arrangements for long periods.

Information Problems

There are at least three contexts in which the problem of costly, limited, or asymmetric information is central to PCT. The first is the claim, derived from the Austrian position in the 'socialist

calculation debate' (Hayek, 1945) of the 1930s and 1940s, that governments could not possibly be able to gather enough information to make accurate judgments about resource flows and production decisions. Information is simply too dispersed, too specific, and too dynamic to allow aggregation.

The second information problem is the 'rational ignorance' of voters. Downs (1957) pointed out that individual voters have at best limited incentives to acquire accurate information about candidates, without which the accuracy of representational choices in a republic is suspect. As a result, institutions such as parties (Aldrich, 1995) or ideologies (Hinich and Munger, 1994) are important components of large, complex political systems. In fact, if Downs is right, democracy would be effectively impossible with parties and ideologies.

Third, there is the micro-level concern about specific local knowledge needed to resolve disputes and impose judicial remedies. As discussed above, the macro problem of organizing the economy is an obstacle to valuing commodities in the aggregate, and in rationing valuable resources in the face of competing uses. But the problem of transaction costs in local disputes over externalities is the micro-level analog, and represents a substantial difficulty for regulatory decisions. As Coase (1960) pointed out that, the very transaction costs that make private negotiations over nuisances and externalities problematic are likely to hamper government efforts to solve the same problem. Again, this problem is related to Austrian economists' (Kirzner, 1985) concerns over the knowledge required to assign the 'correct' value to resources and nuisances. But the problem is even more severe, because of the subjective nature of value, and the requirement that government officials must make interpersonal utility comparisons.

These information problems come together in the so-called revelation problem, long of interest to PCT scholars. After all, there exists a determinate solution to the problem of optimal tax shares for provision of a public good (Lindahl, 1919), but this solution relies on the availability of accurate – and honest – valuations by citizens. There was interest in PCT on the question of demand revelation (Tideman and Tullock, 1976; Tullock, 2006), but the complexity of the tax schemes involved turned out to be prohibitive.

Rent-Seeking

Economists have long believed that competition is good, and more competition is better. For this reason, many economists support antitrust policies that limit the market power of existing firms, because of the deadweight losses associated with pricing above marginal cost, or 'rents.' Harberger (1954) famously disputed whether monopolies really cause that much harm, and offered empirical measures that suggested that the static deadweight losses, at least, were not enormous. There was general agreement that the rectangle of monopoly profits, or rents, was simply a transfer and therefore economically innocuous.

But Tullock (1967) recognized a mechanism by which not just the triangle, but also the rectangle, was actually social costs. The reason is that a 'rent seeker,' or economic agent pursuing the rents of the rectangle of monopoly profits, would be willing to devote resources up to the value of the rectangle to get, and then retain, access to those rents. The resources spent on rent-seeking were consequently not a transfer, but might represent pure deadweight losses. If the activities involved lobbying, bribery, or the creation of asset-specific capital to capture the rent, those resources would be taken away from other productive activities.

Worse, if government has been complicit, creating artificial benefits such as trade barriers against foreign competition, or licensing or other requirements to erect entry barriers domestically, firms competing for these benefits will dissipate much of the benefit. If government can change the rules to create an unfair benefit for one competitor, in terms of access to contracts or patents, competition over that rule change will dissipate a value approaching the expected rent from the benefit.

A business firm might invest in new plant and equipment, achieving lower prices and higher quality in a way that benefits consumers but harms the rest of the industry. The harm to the rest of the industry takes place within the existing rules of competition, and is generally more than offset by the far larger benefits to consumers. But a business firm might also invest in lobbying the government to create new rules, such as protections from competition that raise prices and destroy incentives for innovation. The benefit to the industry results from a political 'investment,' and the harm to consumers is far larger than the benefit to firms and workers.

The literature on rent-seeking has become quite large, and has expanded beyond PCT. The actual term 'rent-seeking' was first used by Krueger (1974). Later work on measuring and refining rent-seeking has included estimates of the proportion of the 'rent-seeking sector' of economies, the size of growth loss to rent-seeking, and other topics (see Rowley et al., 1988; Tollison, 2007).

Human Motivation and the Problem of Institutional Design

PCT is sometimes criticized as being a cynical or oversimplified view of human action. But PCT is, for the most part, self-consciously modest about what it can explain and where it should be applied. The first step in a PCT explanation is deceptively narrow: what would happen if people were self-interested? But it is important to keep track of just what the theory is trying to explain. The goal is to ask what institutions would look like if a very simple model of human behavior were assumed and its implications explored. This is quite different from saying that certain conclusions will be derived, but that these conclusions depend for their validity on the literal correctness of the self-interest assumption.

A clear example is Mayhew (1974). He asks, what would the institutions of the US Congress look like if members of Congress were single-minded seekers of reelection? Then he compares the answer to that 'as if' question against US Congressional institutions one actually observes.

What did he find? There are no important differences. The institutions of Congress one actually observes are indistinguishable from those implied by a consciously oversimplified behavioral assumption of narrow self-interest.

The organization of Congress meets remarkably well the electoral needs of its member. To put it another way, if a group

of planners sat down and tried to design a pair of American national assemblies with the goal of serving members' electoral needs year in and year out, they would be hard pressed to improve on what exists (pp. 81–82).

None of this implies members of Congress are exclusively, or even primarily, selfish. But actual institutions can be explained, at least in part, by a model that allows selfishness. An earlier example, using assumptions much like what later became PCT, is James Madison's description of the problem of institutional design.

Ambition must be made to counteract ambition. The interest of the man must be connected with the constitutional rights of the place. It may be a reflection on human nature, that such devices should be necessary to control the abuses of government. But what is government itself, but the greatest of all reflections on human nature? If men were angels, no government would be necessary. If angels were to govern men, neither external nor internal controls on government would be necessary. In framing a government that is to be administered by men over men, the great difficulty lies in this: one must first enable the government to control the governed; and in the next place oblige it to control itself. A dependence on the people is, no doubt, the primary control on the government; but experience has taught mankind the necessity of auxiliary precautions (Madison, Federalist #10, Rossiter, 1961).

The problem, then, is not whether, or how often, the PCT assumption of self-interest is correct. Rather, the problem is to design institutions that will function even if political actors were motivated by ambition rather than the public interest.

The fact is that PCT has long recognized that the assumption of self-interest is at most one view among many. Often, all that is required is the notion that political actors are purposive, or goal-oriented, and that those purposes or goals motivate the choices and strategies actors select. As Buchanan and Tullock (1963: pp. 16–17, emphasis added) note, the idea of genuine egoism, pure self-interest, as a motivation has always been more interesting to critics – as a straw man – than it has been to proponents.

The first point to be noted is that economic theory does not depend for its validity or its applicability on the presence of the purely economic man. *This man of fiction, who is motivated solely by individual self-interest in all aspects of his behavior, has always represented a caricature designed by those who have sought to criticize rather than to appreciate the genuine contribution that economic analysis can make, and has made, toward a better understanding of organized human activity….*

It is also necessary to emphasize that [PCT] *does not try to explain all human behavior, even all of that which might be called 'economic' in some normally accepted sense of this term. At best, the theory explains only one important part of human activity in this sphere. It examines one relationship among individuals in isolation….*

Empirical Implications and Connections

When James Buchanan won the Nobel Prize in 1986, Alistair Cooke (in his 'Letter from America' program on BBC 4) noted that PCT was committed to the "homely but important truth" that politicians are really no different from the rest of us (quoted in Brennan and Lomasky, 1993: p. 2). The idea that human behavior is of a piece, affected most by differences in incentives and institutions, rather than having entirely different goals and motivations in different contexts, has had an impact beyond the boundaries of traditional PCT.

Some of the most interesting and important work in the last two decades has been in experimental and behavioral political economy, as well as the study of comparative institutions. In addition to James Buchanan, two other past Presidents of the Public Choice Society have been awarded Nobel Prizes: Vernon Smith (2002) and Elinor Ostrom (2009). Smith played a central role in the creation and expansion of the Economic Science Association, which is the flagship organization for presenting work in behavioral economics experiments. And Ostrom played a central role in the creation and expansion of the International Association for the Study of Common Property, which is concerned with institutions for solving common pool resource problems and other problems of capturing gains from cooperation and exchange in nonmarket settings.

As a body of work, PCT is in many ways a counterpoint to the tradition of welfare economics in the 1940s and 1950s, which looked at tax, expenditure, and regulatory policies as solutions to problems of 'market failure'. The counterclaim of the public choice movement is not that markets are perfect. Rather, what PCT does is point out that the logic of 'markets fail, therefore government can do better' is at best incomplete. Each of the six problems described here involve a difficulty that government action has to overcome. Taken together, these problems represent sources of 'government failure', which would have to be balanced against market failure in deciding how a society might best organize itself.

PCT is a direct answer to the assumption of a benevolent government, both in terms of collective action and agency problems. Political groups and officials cannot simply be assumed to act in the public interest. The 'will of the people' may be hard to gauge, and the coercive powers of the state may be very difficult to constrain. Taken together, these observations raise important questions about the 'market failure' justification for state action. The claim is not that market failure is not real; rather, PCT is skeptical that government has the incentives (as noted above) or the information necessary to do better.

Interestingly, these problems had been recognized much earlier, by the very scholar usually credited with originating the idea of 'corrective' taxes and subsidies as a means of correcting market failures. A.C. Pigou (1920) aptly summarized the humility that PCT would urge on planners and government officials, and recognized the inherent limitations of state action:

> It is not sufficient to contrast the imperfect adjustments of unfettered enterprise with the best adjustment that economists in their studies can imagine. For one cannot expect that any State authority will attain, or even wholeheartedly seek, that ideal. Such authorities are liable alike to ignorance, to sectional pressure, and to personal corruption by private interest. A loud-voiced part of their constituents, if organized for votes, may easily outweigh the whole. (p. 296)

Public Goods: International

Abstract

International public goods are goods that are accessible to all at the international level, the consumption of which by one individual does not reduce the possibility of consumption by other individuals. However, there are few public goods of this pure type. Instead, nearly all are characterized by mostly unlimited accessibility and simultaneous rival consumption, i.e., the use of the resource by one individual reduces the possibilities for others to consume this good. These types of goods are called common-pool resources. A number of institutional possibilities exist to secure the provision of public goods and common-pool resources. In what follows, public goods will first be defined, and then different paths to the development of institutional answers to collective action problems will be presented, before different institutional modes of provision of public goods and common-pool resources as well as their possible implications will be discussed.

International public goods are goods that are accessible to all at the international level, the consumption of which by one individual does not reduce the possibility of consumption by other individuals. However, there are few public goods of this pure type. Instead, nearly all are characterized by mostly unlimited accessibility and simultaneous rival consumption, i.e., the use of the resource by one individual reduces the possibilities for others to consume this good. These types of goods are called common-pool resources. Where there is free accessibility and rival consumption, a collective action problem or social dilemma arises: how can the individual user be prevented from using the limited resource and jeopardizing the long-term utility of all as a result of maximizing their own short-term individual interest?

A number of institutional possibilities exist to secure the provision of public goods and common-pool resources. However, the possibilities for collective action within a specific institutional context available at national level – such as legal prescriptions imposed by majority decision in order to force individual actors to comply with a scheme of collective action – are not all applicable at the international level because of nation-state sovereignty. In what follows, public goods will first be defined, and then different paths to the development of institutional answers to collective action problems will be presented, before different institutional modes of provision of public goods and common-pool resources as well as their possible implications will be discussed.

Definition of Public Goods

Public goods and common-pool resources – as stated above – may be defined by the analytic economic criteria of universal accessibility and (non)rival consumption. These attributes may be properties that are inherent to the goods themselves, or they may be properties that are attributed to goods through societal consensus and/or political decision. In the older economic literature, the central attributes of public goods – nonexcludability and nonrivalry (Samuelson 1954; Musgrave and Musgrave 1976) – have been regarded as sources of market failure, from which the need for state intervention has been derived. The problem with common-pool resources and public goods lies in their limited excludability. As a result, prices cannot be charged and hence private provision through the market cannot be relied upon.

More recently, economic theory (Cornes and Sandler, 1996) has argued in a more differentiated way that there are exceptions to this rule when a particular actor has an incentive to provide a public good irrespective of the free-riding behavior of other beneficiaries. The same holds true when, in the case of a common-pool resource, the stakes of provision are high enough to induce cooperation among actors (Cornes and Sandler, 1996). Only in cases where the private provision of common goods fails are governments called upon to remedy the market failure (Bator, 1958). Another perspective from which public goods can be viewed is starting from the phenomenon that some market activities generate external effects. Positive, as well as negative, external effects are not part of the actor's economic calculation and, as a result, they are under- or overproduced from an aggregate view. In the traditional perspective, externalities are seen as by-products of economic activities and internalization of externalities traditionally has been viewed as a government task (Pigou, 1920). However, in the 1960s, a new interpretation started to dominate the economic literature. According to this view, Pareto-relevant externalities are internalized through market forces if property rights are well defined and transaction costs are sufficiently low (Coase, 1960; Buchanan and Stubblebine, 1962).

While economic theory views the properties of a public good as inherent attributes of such a good from which a specific institutional form of provision is deduced, political science goes beyond this notion to insist additionally on a process view of common goods. It argues that what constitutes such a good and how it is provided for institutionally depends on specific situational and technological conditions, and, moreover, is determined in a political and social process. First, it is not clear in many cases what constitutes a public good or a common-pool resource in so far as there are no absolute and objective criteria for defining them in a general sense. Instead, what constitutes a public good depends in part on the specific situational context of provision and consumption of the good, and its technical properties.

Thus, the importance of a specific situational context for the definition of a good as a public good in terms of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.75045-8

nonexcludability and nonrival consumption is illustrated by the example of the protection offered by the ozone layer vis-à-vis radiation for sunbathers. This is a public good in the classical sense. One sunbather enjoying the sun does not impinge upon the protection offered to other sunbathers. In this sense, the ozone layer is a public good, accessible to all with nonrival consumption. In another sense, however, it may be perceived as a common-pool resource. Seen in terms of the relationship between producers and sunbathers, and given that scientific research has identified a problem of scarcity in the ozone layer, certain productive activities, such as the production of refrigerators with chlorofluorocarbons, diminish the protective quality of the ozone layer and jeopardize the protection offered to all. This is rival consumption. In this specific context, the ozone layer constitutes a common-pool resource that is accessible to all and is depletable (Snidal, 1984).

Technological innovation may force a reconsideration of the definition of a public good in cases where a good, which had hitherto been regarded as universally accessible and nondiminishable, has been rendered potentially excludable. A case in point is broadcasting. This good used to be accessible to all and was of nonexcludable nature, but as a result of technological change, access to the good can now be limited to those paying for the service via a telematic coding system. Put in different terms the transaction costs for establishing property rights were reduced drastically by technological progress so that the gains from excluding free riders and the precise allocation of user costs now exceed the costs of establishing property rights. Second, the definition of what constitutes a public good and what does not may not necessarily be determined by 'objective' characteristics, but instead by political and social definition. There are huge cultural variations across polities and time as to what is considered a public good or common-pool resource and what is a private good.

Thus, universal and free health care may be formulated as a political goal and consequently be considered as a common-pool resource in one polity. But in another, the same service may be regarded as a private good that each individual has to buy on the market. In the same way, policy makers in one society may decide that its provision should be left entirely to the buying power of the individual through the market. Hence, what constitutes a public good or common-pool resource can be answered either in terms of analytic economic criteria or in terms of a process of social and political definition. Once a good has been identified as a public good or as a common-pool resource, the institutional mode of provision of the good has to be determined.

The Provision of Institutional Answers to a Collective Action Problem

Different paths may lead to an institutional answer for a stable solution for providing public goods at the international level. The solutions may be designed intentionally, as is the case of international agreements. They may develop without being planned, as in a case of spontaneous coordination, for example, in the case of the standardization of products. Either way, once in place, they develop an institutional dynamism of their own and over a period of time they may transform the processes in the institution and, in turn, transform the preferences of the actors involved. The intentional formulation of an institutional solution to a public good problem may presuppose an acute awareness of an existing social dilemma and a need for collective action where there is cross-boundary problem interdependence. For example, in the case of an imminent cross-border environmental problem, an international conference will be convened that seeks to develop a format of cooperation.

After a lengthy process of bargaining, institutional answers for solving the problem will be found and agreed. All those involved in the negotiations will seek to maximize their own interests, for example, by minimizing the implicated costs. In other words, institutional solutions to collective action problems are interpreted in terms of their distributional impacts on the actors involved (Knight, 1995). In the great majority of cases, the negotiators do not all enjoy the same degree of power, and in the event of an agreement not being reached, the stronger actors may take up a fallback position. While a solution may be desirable for them, they may not consider it vital. In other words, they have more resources for negotiating an institutional solution. This route to an institutional solution, i.e., interest-oriented, power-based negotiation with a view to the distributional results, generally applies where the interests at stake are clear cut and substantial.

A case in point is the negotiation of CO_2 emission limits at international climate conferences. All the states engaged in the bargaining process, to find an institutional solution for reducing emissions, view the process in terms of its distributional impacts on the market position of domestic industries, and so forth. However, there are situations where collective action problems need to be solved and the actors involved do not really appreciate the nature of the problem at hand, much less which interests are at stake. Consequently, the preferences of the actors involved are uncertain. In such situations deliberation, exchange of arguments, and persuasion will prevail as the actors strive to reach, at best, a common perspective on the problem at hand together with possible solutions; or as a minimum, to establish clarity as to the different stakes involved (Knight and Johnson, 1994). Only then does interest-oriented bargaining follow and asymmetries of interests and power come into play. Cases in point are complex environmental problems or the problem of providing more transparency and certainty in financial markets.

The second avenue for developing an institutional solution to a collective action problem is that of the spontaneous emergence, rather than the intentional development, of a solution in a planned social interaction at international level. Here, the strategic uncertainty as to the preferences of other actors promotes behavior likely to resolve a social dilemma. It makes sense to shape other actors' perceptions of one's preferences and to give signals of willingness to coordinate and be trustworthy. These signals enable like-minded actors to locate others who are equally so, and who can in turn build up a reputation for responding cooperatively to trust (Bates, 1988). Because actors prefer coordination as one of the outcomes, as opposed to noncoordination, they will use whatever salient information (focal point) they have in order to achieve that coordination (Schelling, 1960). In time, other actors will follow suit, and a social convention is established,

which provides information about the future actions of others (Knight, 1995). The focal point may be relatively contingent, but henceforth serves as a point of reference for future coordinating actions (Calvert, 1986; Schelling, 1960).

Third, irrespective of the path along which an institutional solution develops, be it design or spontaneous emergence, once established, it gains a dynamism of its own. The institutional process then begins to develop its own rules beyond the formal and informal rules originally instituted, or interprets the original rules in the light of the day-to-day need to make decisions, thereby transforming and developing those rules incrementally (March and Olsen, 1989). This process may change the preferences of the actors involved. Not only the paths of development of an institutional solution to secure the provision of a public good or a common-pool resource but also the specific context in which it is shaped and the institutional arrangements in which it is embedded have been discussed in the literature.

The Context and Institutional Mode of Provision

What is the general context and what are the more specific institutional and instrumental conditions in which the provision of a public good and a common-pool resource occurs? The overall question is: under which conditions do particular institutional arrangements apply particular instruments to produce favorable results for providing public goods at the international level? With respect to the overall context, it is argued that the greater the number of participants involved in an attempt to resolve a social dilemma and the greater the heterogeneity of the actors involved, the greater is the difficulty in arriving at a solution. In this sense, the prospects of an efficient solution to collective action problems for agreements at the international level, with its heterogeneous actors and large numbers of participants, would appear to be bleak.

However, as has been pointed out (Ostrom, 1990; Martin, 1994; Snidal, 1984), this relationship is not as simple as it first appears. Heterogeneity may constitute a precondition for actors to take the lead in organizing collective action because they have a specifically strong incentive for this action to be successful. Thus, the United States has repeatedly acted as a hegemonic actor in cooperating with Western public and private actors when it comes to solving collective action problems such as sharing banking information to enable countries to uncover money laundering (Schmidt, 1995). Furthermore, the problem of coordinating an unwieldy number of actors is often alleviated by organizing the participants into groups according to commonly shared criteria. Each group is represented by a speaker, as in the case of climate negotiations, thereby reducing the number of actors sitting at the bargaining table. Moreover, the extent to which homogeneity facilitates negotiations in collective action problems depends upon the nature of the homogeneity: if all actors are intent on having the same resource, homogeneity may render agreement difficult. If, by contrast, the preferences of actors differ over time and in intensity, they may be made complementary through issue linkage (Martin, 1994).

Beyond the general context conditions, various institutional arrangements and instruments are applied in the provision of public goods and common-pool resources at the international level that determine the degree of success in solving the collective action problem. The institutional arrangement denotes the structure and the nature of the relationship among the actors involved; the instruments that are applied define how the desired behavior of the target actor is to be elicited. The basic types of institutional settings for providing public goods are hierarchy, negotiation, societal self-regulation, and markets (Mayntz, 1997; Scharpf, 1999). Hierarchy is an arrangement in which a central actor (government) has an electoral mandate that permits it to legislate specific provisions, such as the statutory requirement to use a fully regulated catalytic converter, with noncompliance being sanctioned in order to protect the quality of ambient air. Thus, legal obligation is backed up by a bureaucratic apparatus to ensure implementation.

In an international context, hierarchy as an institutional arrangement for providing public goods and protecting common-pool resources can only be applied to a very limited extent. However, even in international negotiations among sovereign states seeking to solve a collective action problem, a certain amount of initiative needs to be taken by one or a group of actors if public goods are to be provided jointly. As a result, there is power being yielded by central actors in varying degrees in order to facilitate cooperation. Thus, a central body may consist of member actors who only make framework decisions that subsequently are made more specific by actors at the decentral level, or the central body may delegate power to members to implement the decisions. However, it is also conceivable that the outcome of autonomous actors cooperating voluntarily is strict implementation by command-and-control once a decision is agreed. Depending on whether the decision is vaguely, as opposed to precisely, formulated, the ensuing latitude for such actors is either great or little. Power to sanction noncompliance may again be vested in a central body or, alternatively, in decentral bodies (Martin, 1994).

Another important institutional setting in which solutions to collective action problems at the international level are found is negotiations in bipartite, tripartite, or multipartite actor constellations. However, it can often be linked to elements of various forms of hierarchy. Thus, if negotiations are not successful in bringing about a solution to a problem, actors may move out of the arena and turn to a court or a tribunal for a ruling in order to overcome the conflict. In anticipating this possibility, actors may be more willing to compromise. Thus, in the European dispute over social policy, if social partners do not negotiate an agreement successfully, the Commission may propose legislation for submission to the Council of Ministers. The 'shadow of hierarchy' (Scharpf, 1997) speeds up negotiations. Some actors are particularly apt at brokering agreements in negotiations at international level in order to bring about a common solution. In the European context, the Commission has played a preeminent role in hammering out such agreements by acting as a policy entrepreneur and broker in different arenas, bargaining with various actors simultaneously in order to develop solutions acceptable to all, for example, by proposing package deals and compensation payments. (Grande, 1995).

Yet another institutional arrangement is the self-organization and self-regulation of actors. Self-regulation in providing a public good or common-pool resource implies that

the same actors who make joint decisions about how to provide the common good also implement these decisions. The actors concerned build on the motivation, expertise, and resources of the actors immediately affected in order to provide public goods (Mayntz and Scharpf, 1995). These forms of self-governance are also linked frequently to elements of hierarchy, such as the possibility of appeal to a third-party tribunal (Ostrom, 1990). Finally, markets may serve as an institutional context for the provision of public goods and common-pool resources under specific conditions, for example, when a group of actors have such high stakes that they engage in the provision. It has been increasingly claimed that quasimarkets should be created to provide public goods and common-pool resources (Le Grand, 1991).

Thus, many Western countries have promoted the liberalization of state monopolies in the provision of network utilities. However, a pure form of market as an institutional arrangement for providing public goods and common-pool resources can rarely be found either. Rather – as, for example, in the case of the provision of network utilities – markets are regulated at two levels: in terms of market creation to guarantee competition on the one hand, and at the level of market correction as regards 'service public' obligations to guarantee the accessibility and affordability of these services on the other hand. Here – as with other institutional arrangements – two or three different types of institutional arrangements for providing public goods or common-pool resources are combined rather than existing separately as pure forms.

Moreover, institutional solutions for the usage of common-pool resources may be developed if different types of property rights are distinguished. Schlager and Ostrom (1992) distinguish the 'right of access' to a defined physical area and its nonrival use from the 'right of withdrawal' of resource units; the 'right of management' of a resource (i.e., regulate its use); the 'right of exclusion,' i.e., to determine who has access; and the 'right of alienation,' i.e., the right to sell or lease management and exclusion rights. Thus, in the case of groundwater basins, individual actors may have a withdrawal right of a specific quantity of water, but the groundwater basin may be managed by government (Ostrom, 2002: p. 49).

A further, more contextual institutional mechanism for solving collective action problems is the development of 'social capital' and trust among the actors concerned (Taylor, 1996; Hardin, 1993). The underlying notion is that one can trust the others involved to cooperate in the provision of a public good. Trusting others is reasonable because it is in their interest to be trustworthy in a specific situation in which a social dilemma is to be overcome. One's own trust depends on the interest of the trusted (Hardin, 1999). The instruments of command-and-control, bargaining, setting incentives, persuasion, and information are often closely linked to the institutional settings in which they are applied. Thus, command-and-control is often applied in a hierarchical context where a government authority requires the regulatees to behave in a particular way and where sanctions are applied in cases of noncompliance. However, a majority decision can also be made in favor of applying incentives.

Hence, hierarchy may be linked to instruments other than command-and-control. In the institutional setting of negotiation in bi-, tri-, and multipartist settings, bargaining, together with issue linkage, compensation payments, and compromises are the main instruments used to reach agreement, while deliberation and argument also play an important part. The negotiation process may, however, also result in the application of a strict prescription of behavior linked with the levying of fines. Incentives are set in the institutional environment of the market. Trust would be linked to information and persuasion.

Implementation Agreement

Implementation agreement on a joint institutional solution to provide a public good does not automatically guarantee its implementation. The path from decision making to the final realization of the measure is a long one, and many obstacles may prevent it from being a smooth process (Pressman and Wildavsky, 1973; Mayntz, 1983; Windhoff-Heritier, 1980).

At the international level, typically we are faced with the situation that the definition of the goods and institutional solutions for providing the public good or common-pool resource occur at international level, while implementation takes place at the national level. This may raise particular problems of compliance. Thus, for example, if an international environmental agreement stipulates the extent and time span for a reduction in CO emissions, this does not mean that the signatory states, in cooperation with industry, will necessarily honor their obligations. Research on implementation concludes that solutions for providing public goods that are redistributive in nature have little chance of being realized, whereas solutions with distributive outcomes, where all stand to win, meet with fewer difficulties. This applies as long as the redistributive solutions do not rely on hierarchy command-and-control that prevents actors who are adversely affected by the decision from trying to change the contents of the decision in the course of implementation, and as long as those who are to benefit from the potential solution do not mobilize in order to exert pressure for a speedy implementation process (Windhoff-Heritier, 1980).

However, since hierarchical guidance and command-and-control can only be used to a limited extent in international governance, effective implementation depends much more on setting incentives which induce actors, over whom there is no hierarchical control, to comply with the agreed solution. Alternatively, it depends on societal mobilization where the actors profiting from the agreement press those who resist implementation into compliance. The same effect may be achieved if an agreed provision is deeply embedded in existing societal value systems. Furthermore, by using reputational mechanisms parties which do not comply are 'named and shamed' into compliance. The noncompliance of a state would result in the loss of reputation.

Outcomes and Impact of the Institutional Provision of Public Goods

A final question relates to the outcomes and impacts of specific institutional provision of a public good at the international level. What are the policy outcomes of such a solution and how

does it affect existing governance structures? The first question addresses the problem-solving capacity of an institutional solution, i.e., the performance of the institutional setting that has been created and the instruments applied in solving the problem. Thus, the question may be raised: does an international environmental agreement help protect endangered natural resources? Since institutional solutions are largely negotiated with a view to their potential distributional outcomes, their de facto distributive effects must be identified. Who gains and who loses on account of a specific institutional solution, and what does this mean in terms of the stability of the chosen solution? The second aspect relates to the fact that specific institutional solutions to public good problems across boundaries affect existing governmental and governance structures. Thus, the formal decision-making powers and the de facto power of national actors are changed by specific institutional solutions to problems.

A case in point is the attempts of the European Union to solve collective action problems in environmental policy that have challenged the competencies of subnational actors in the member states. Similarly, the de facto involvement of Euro associations in policy shaping has implied a loss of political power of national associations. Finally, the question must be raised as to how the overall structure and functions of the traditional state change in an environment where public goods are provided by forms of international governance. Does it imply the demise of the traditional state (Majone, 1996; Grande and Eberlein, 1999) in direction of the regulatory state?

Abstract

Behavioral and social science research and theories are relevant to promoting health and preventing disease in the population. This article discusses the major health challenges confronting developed and developing countries, the contribution of social and behavioral factors to current global health challenges, and current approaches to addressing health problems. Finally, it considers the importance of using social and behavioral theories and models to providing a comprehensive understanding of all the determinants and influences relevant to a particular health issue, and informing the development of efficacious, practitioner-delivered lifestyle–change interventions to address these issues at a public health and societal level.

This article focuses on the extent to which behavioral and social science research and theories are relevant to the challenge of promoting health and preventing disease in the whole population. An overview is provided of the major health challenges confronting developed and developing countries, including a discussion of the contribution made by social and behavioral factors to these global health challenges. It is important to note some key differences between the so-called individual or high-risk approach to addressing health problems, and the whole-of-community or population approach. The 'high-risk' approach, used to develop efficacious, intensive, practitioner-delivered lifestyle–change interventions for individuals, needs to be integrated within a broader public health approach. The latter approach involves a consideration of the whole spectrum of sociobehavioral and environmental factors that are relevant determinants of health to promote health and prevent disease. The importance of the wider dissemination and uptake of interventions at an institutional or policy level is also discussed. Social and behavioral theories and models are very important in public health; they not only help provide a more complete understanding of all of the determinants and influences relevant to a particular health issue, but are also very important for informing how to address the health issue at a public health and societal level.

What Is Public Health?

Public health has been classically defined as

> "… the combination of science, skills and beliefs that are directed to the maintenance and improvement of the health of all people through collective or social actions. The programs, services, and institutions involved emphasize the prevention of disease and the health needs of the population as a whole. Public health activities change with changing technology and values, but the goals remain the same: to reduce the amount of disease, premature death and disability in the population."
>
> Last, 1995

Health was defined by the World Health Organization (WHO) more than 60 years ago as "a state of complete mental, physical, and social well-being, and not merely the absence of disease or infirmity." By this definition, health is more than just a physical state and is inextricably linked to personal well-being and potential, and incorporates many other dimensions of human experience, such as quality of life, psychological health, and social well-being. *Public health* is different from other fields of health and medicine as it strongly emphasizes the promotion of health and well-being and the prevention of disease, illness, and disability at the population level. *Populations* are groups of individuals with some similar characteristic(s) that unify them in some way, such as people living in rural areas, older people, women, an indigenous group, or the population of a specific region or country.

Contemporary public health is particularly concerned with those sections of the population who are under- or poorly served by traditional health services and, consequently, are most disadvantaged and vulnerable in terms of their health. Because such disadvantage or vulnerability usually has its origins in the very early years of childhood and/or is related to an individual or a population subgroup's social and economic circumstances, public health is therefore very concerned with the more upstream or distal (i.e., distant from the person), social, physical, economic, and environmental determinants of a person's health, in addition to the more proximal determinants (i.e., closer to the person), such as lifestyle risk factors, health behaviors, and biological factors.

Preventing any disease is commonly grouped into three levels, named for the stages of disease that they target; primary (pre-disease), secondary (latent disease), and tertiary prevention (symptomatic disease). *Primary prevention* aims to reduce both the incidence and prevalence of a disease before it occurs. For example, encouraging people to protect themselves from ultraviolet radiation or tobacco prevention and health promotion programs which target young people are examples of this level of prevention. *Secondary prevention* (or early detection) refers to the situation after a disease has started to occur, but before the person has noticed anything is wrong. The goal of secondary prevention is to find and treat a disease early – such as cardiovascular disease or diabetes – and in many cases, the disease can then either be cured or the risk of progression can be significantly reduced. *Tertiary prevention* targets people who are already experiencing symptoms of

a disease or diseases and thus aims to reduce the complications associated with poor health and minimizing disability and suffering, such as cardiac rehabilitation programs for patients after a heart attack. There is also a fourth level of prevention, *primordial prevention*, which involves actions and measures to prevent the emergence of risk factors in the form of environmental, economic, social, and cultural patterns of living. For example, many adult health problems, such as obesity and hypertension, have their origins in childhood, because this is the time when the determinants of lifestyle are developing. Subsequently, improving the social and economic circumstances of families during these early years can have a profound influence on later health. Sometimes the boundaries of prevention strategies are indistinct, and it can be common for a given intervention to address a combination of the primary, secondary, and tertiary levels.

The World Health Organization recommends the combined use of population (or mass) and high-risk strategies for prevention. The 'high-risk' strategy aims to provide preventive care to individuals at special risk; hence it requires the detection of individuals with high risk. The *population strategy* is directed at the whole population, or subgroups in the population, irrespective of their individual risk levels. For example, research has demonstrated even a small reduction in the average blood pressure or the serum cholesterol of a population can produce a large reduction in the incidence of cardiovascular disease. Health promotion strategies are often very important for prevention and the WHO definition for health promotion is "the process of enabling people to increase control over the determinants of health and thereby improve their health" (World Health Organisation, 2005). Successful prevention depends upon the following: a knowledge of causation and the determinants; an understanding of the dynamics of transmission; identification of risk factors and risk groups; availability of evidence-based preventive or early detection and treatment measures; an organization and systems for delivering their measures to appropriate persons or groups; and continuous monitoring and evaluation and further development of the strategies that have been implemented.

The application of behavioral and social science theories and methods to prevention can occur at multiple levels and in many different settings in the community. Many public health initiatives are aimed at the individual or interpersonal level, and are delivered through the primary care setting, workplaces, and schools. Such programs typically have a low reach, in that only a limited number of people are impacted on by, and/or have access to the programs. However, these programs can have high levels of exposure for the individuals and can be quite intensive. Other programs can be organized and implemented through whole organizations or systems. Finally, community-wide or societal-level interventions may involve mass or social media, policy, or legislative action at a national or governmental level, and these can have a very large reach. However, program exposure for any given individual is typically quite low.

The practice of public health is therefore very broad and can include the delivery of many different types of programs and services throughout the community. It can include efforts to reduce health disparities, increase access to health services, improve childhood rates of immunization, control the spread of HIV/AIDS, reduce uptake of smoking by young people, and implement legislation and policies to improve the quality of water and food supplies, reduce the occurrence of motor vehicle accidents, and reduce pollution. In fact, the overall health and well-being of the population is more directly related to the effective and widespread implementation of these kinds of efforts, than it is by the society's direct investment in direct health-care delivery.

This article discusses the extent to which theories and models from the behavioral and social sciences can better underpin the understanding and practice of public health. The following sections of this article provide a brief overview of the major public health problems and challenges confronting both developed and developing countries; the contribution made by social and behavioral factors to many of these health problems; and how social and behavioral theories and models can be usefully applied to the development, implementation, and evaluation of public health programs.

Trends in the Global Burden of Disease

The past 100 years have seen substantial change in health and the patterns of disease burden around the world. The findings of the Global Burden of Disease Study 2010 resulted from the collaborative efforts of 486 scientists from 302 institutions in 50 countries and it has made a very important contribution to our understanding of present and future health priorities for specific countries and the global community (Horton, 2012). Expanded in scope since the first study of the global burden of disease completed in 1990, in which 107 diseases and injuries and 10 risk factors were assessed, the GBD 2010 included 235 causes of death and 67 risk factors. This has facilitated the comparison of diseases which cause early death with those that cause prolonged suffering or disability in any country or region of the world.

Disease burden refers to the impact of diseases, injuries, and risk factors as measured by financial cost, mortality, morbidity, and/or other indicators. It is often quantified in terms of quality-adjusted life years (QALYs) or disability-adjusted life years (DALYs), both of which measure the number of years lost due to disease. One DALY can be thought of as 1 year of healthy life lost, and the overall disease burden can be thought of as a measure of the gap between current health status and the ideal health status. Such measures allow for a comparison of difference causes of disease burden, and they can also be used to evaluate the possible impacts of health intervention for similar or different causes. The WHO has now also provided a set of detailed guidelines for measuring disease burden.

The findings GBD 2010 (Horton, 2012) also allowed a comparison of health life expectancy, a summary measure which captures mortality and nonfatal outcomes in a single measure, between countries from 1990 to 2010. Contributions of changes in child mortality, adult mortality, and disability to overall change in population health between 1990 and 2010 were also considered. Findings revealed that in 2010, global healthy life expectancy at birth was 59 years for males and approximately 63 years for females, and across countries in 2010, life expectancy at birth ranged from almost 28 years in Haiti to 71 years in Japan for males, and 37 and 75 years for

females in Haiti and Japan, respectively (Salomon et al., 2012). In the past 20 years healthy life expectancy has increased by 5 years or more for males in 48 countries compared with 43 countries for females. However, healthy life expectancy decreased for males in 22 countries compared with 11 countries for females. Worthy of note is that increases in life expectancy have corresponded with an increase in the number of healthy years lost to disability (YLDs) in most countries. This finding has implications for health planning and health-care expenditure. That is, although substantial progress has been made in terms of the reduction of mortality over the past two decades, comparatively little improvement has been made in reducing the overall effect of nonfatal disease and injury on population health. Of course, this provides a very strong argument for the importance of prevention.

GBD 2010 findings also reveal that although almost 53 million deaths occurred in 2010, up from approximately 46 million deaths in 1990, some very important progress has been made in global health and the health of the majority of countries. For example, life expectancies are increasing for men and women and a greater proportion of deaths are taking place among people aged 70 and older (Horton, 2012). The burdens of HIV and malaria are falling, and fewer children aged 5 years or less are dying (Horton, 2012). The number of deaths attributable to communicable, maternal, neonatal, and nutritional causes were also down from those attributed to these causes in 1990, due largely to decreases in mortality from diarrheal disease (2.5–1.4 million), lower respiratory infections (3.4–2.8 million), neonatal disorders (3.1–2.2 million), measles (0.6–0.13 million), and tetanus (0.3–0.06 million) (Horton, 2012). Furthermore, infectious diseases control is improving in most countries.

Despite this progress, old threats remain and new threats have emerged. In developing countries, major public health problems continue to include infectious diseases, undernutrition, and complications of childbirth, as well as the increasing prevalence of chronic diseases such as cardiovascular disease, cancer, and diabetes. In Sub-Saharan Africa communicable, maternal, neonatal, and nutritional causes still account for 76% of premature mortality in 2010, and newborn, and child mortality, and various vaccine-preventable and other communicable diseases remain urgent concerns (Horton, 2012). Furthermore, the considerable impact of HIV/AIDS on mortality and disability in most developing regions in 2010 is still of concern, as it is now the fifth leading cause of DALYs worldwide (up from 33rd in 1990; a 351% increase) (Murray et al., 2012).

The increasing prevalence of chronic disease is a significant new threat with blood pressure identified as the biggest global risk factor for disease, closely followed by tobacco, alcohol, and poor diet. Deaths attributable to noncommunicable diseases rose from approximately 8 million between 1990 and 2010, to account for two of every three deaths worldwide by 2010. Specifically, 8 million people died from cancer in 2010, 38% more than two decades ago, ischemic heart disease and stroke collectively accounted for one in four deaths worldwide, compared with one in five in 1990, and deaths due to diabetes (1.3 million) were double that in 1990. Deaths due to injuries (5.1 million) were marginally higher in 2010 compared with 1990, a figure driven by a 46% rise in deaths worldwide due to road traffic accidents. In short, ischemic heart disease, stroke, chronic obstructive pulmonary disease, lower respiratory infections, lung cancer, and HIV/AIDS were the leading causes of death in 2010.

Other emerging areas of concern are the increasingly widespread and rising prevalence of diabetes in China and other low- or middle-income countries (Rawal et al., 2012), such as India, Russia, Brazil, Pakistan, Indonesia, and Bangladesh, and the very large unrecognized burden of mental illness in developed and developing countries (Murray et al., 2012). A recent systematic review revealed an increase in diabetes mellitus prevalence from 2.6 to 9.7% in China over the period of 2000–2010 (Li et al., 2012). This finding, combined with the increasing prevalence of undiagnosed, untreated, and suboptimally managed diabetes and prediabetes in China and a population of 1.3 billion people, is cause for concern. In regards to mental illness, results of the GBD 2010 revealed that mental and substance use disorders accounted for approximately 7% of DALYs globally, 8.6 million of all years of life lost (YLL), and are the leading cause of years lived with disability (YLD)s worldwide. The burden of mental and substance use disorders increased by approximately 40% between 1990 and 2010, a figure largely driven by population growth and aging (Whiteford et al., 2013). These findings suggest that mental and substance use disorders pose a significant challenge for health systems in developed and developing regions, and the prevention and treatment of mental and substance use disorders is vital if improvements in population health are to be achieved.

With more people spending more years of their lives with more illnesses, disability from disease and injury is also becoming an increasingly important public health issue. Women are impacted on especially hard by disability with those aged 15–65 years losing more healthy life to disability than men. Although global DALYs remained stable from 1990 to 2010, an important shift occurred in DALY composition with the contribution of deaths and disability among children (aged 5 years and younger) declining from 41% of global DALYs to 25%. YLLs typically account for about half of disease burden in more developed regions (high-income Asia Pacific, Western Europe, high-income North America, and Australasia), rising to over 80% of DALYs in sub-Saharan Africa. Changes in DALYs over the past 20 years were observed for communicable, maternal, neonatal, and nutritional disorders, as well as noncommunicable diseases, and injuries. Furthermore, ischemic heart disease became the leading cause of DALYs worldwide in 2010, up from fourth in 1990, followed by lower respiratory infections (first in 1990), stroke (fifth in 1990), diarrheal diseases (second in 1990), and HIV/AIDS (33rd in 1990). Other significant contributors to global DALYs were major depressive disorder (up 37%) and road injuries (up 34%). In summary, the global disease burden has continued to shift away from communicable to noncommunicable diseases and from premature death to years lived with disability (YLDs). Furthermore, population aging has dramatically changed the global burden of illness worldwide, hastened by improvements in health related to increases in income and reductions in family sizes.

Publications which continually update the GBD estimates are an important source of information for framing health

policies and objectives not just globally but also within specific countries (Murray et al., 2013). For example, the findings of GBD 2010 suggest rising burden chronic conditions and their comorbidities, and the shift away from communicable to noncommunicable diseases and from premature death to years lived with disability (YLDs), particularly in developing or low- and middle-income countries, are significant problems global public health needs to address. In short, disability from disease and injury has become an increasingly important consideration for all health systems as more people will be spending more years of their lives with more illnesses, and suggests a need to focus on the growing burden of noncommunicable diseases and to make a shift from preventing premature death to reducing years lived with chronic illnesses and debilitating conditions (Murray et al., 2012). However, the small evidence base from developing countries is underdeveloped which serves to highlight the need for appropriate cultural adaptation/translation of programs based on social and behavioral models and theories, from more developed settings.

Theories and Models

Understanding the alterable causes of the burden of disease can help inform responses to these challenges nationally, regionally, and internationally, as well as within population subgroups. There are numerous factors which explain the changing patterns of morbidity, mortality, and the spread of disease, globally and between regions and countries, relating to population growth, aging and changes to family, social structures, education and reproductive patterns, and changes in ecological and living environments. An evidence base for these multilevel determinants of health has been extensively developed over the past decade (Roux, 2008), in particular, particularly the important relationships between behavior and health. Fisher et al. (2011) have recently reviewed the central role that behavior has in health and the importance of behavioral interventions to prevent disease, improve management of existing disease, increase quality of life, and reduce health-care costs.

Mokdad et al. (2004) demonstrated the relative contribution of alterable health behaviors and social factors to mortality and morbidity in the United States. They concluded that the primary causes of death in 2000 were tobacco and alcohol use, poor diet, and physical inactivity (World Health Organisation, 2005); however, the conditions of the society were also very important as more fundamental causes of health. More recently, the United States Centers for Disease Control and Prevention released a key report estimating that 14 of the top 15 causes of death in the United States are attributable to modifiable behaviors, including physical inactivity, diet, smoking, alcohol and other drug use, injury control, sun protective behaviors, appropriate use of medicines, immunization, sexual and reproductive health, oral hygiene, and mental health (Heron et al., 2009). An increased understanding of the social, economic, and environmental influences on behaviors leading to health (and ill health) from an individual to a neighborhood/community level and to a global level is consistent with a socioecological model of health that can also be used to understand the rapid increase in chronic NCDs reflected by tobacco, poor diet, physical inactivity, and sedentariness. These findings from a considerable amount of social and behavioral epidemiologic research conducted over the past 40 years demonstrate that a substantial part of the global disease burden is attributable to these multiple levels of influences from the society where we live. This underlines the importance of gaining more of an understanding of the social, environmental, and other determinants of human behavior and how these can be influenced and changed. Theories and models are very important for this improved understanding.

Theories and models from the social and behavioral sciences not only help to explain health-related behaviors and their downstream and more upstream determinants, they can also help guide the development of interventions to influence and change both the determinants of and health-related behaviors themselves and, thereby, improve health of individuals and populations. Theories can also help understand adherence to a health regimen, identify the kinds of information and other details needed to develop effective intervention programs, provide guidelines on effective communication, and identify barriers to be overcome in implementing an intervention.

This article adopts a widespread definition of theory (Glanz et al., 2008), by which a theory is seen as a set of related concepts, definitions, and assumptions about relations between concepts that allow understanding events or situations in a systematic way. The most important notions perhaps are that theories can be applied to multiple problems and they should also be testable, which means that we can generate and examine data that tells us something about how well a theory is suited to explain a specific public health problem. This means that we should select theories (or elements of theories) on the basis of the evidence of such tests of how well they explain and predict a specific problem rather than their face validity or what might appear plausible. Theories can be useful for understanding the determinants of behavior and how to improve health at multiple levels, that is, at an individual, interpersonal, institutional/organizational, community, and/or societal level.

Theories can also be used as basis for public health measures to specific populations to increase effectiveness. For example, target group-specific theories such as the Gelberg–Andersen behavioral model for vulnerable populations (Gelberg et al., 2000) explicitly include frequent behavioral problems in vulnerable populations as predisposing variables that impact on health-care utilization. On the other hand, demographic characteristics (e.g., age, sex, cultural background, behavioral characteristics) of the target group can be taken into account in identifying the most promising theory-based methods.

Furthermore, an important distinction can be made between theories that explain behavior (e.g., 'The Theory of Planned Behavior,' Ajzen, 1991) and theories that explain change in individuals and organizations (e.g., 'Diffusion of Innovations,' theory Oldenburg and Glanz, 2008). The former are useful in outlining factors that are for example responsible for engaging in a specific behavior, the latter are useful in identifying factors that promote change.

On the level of individual behavior, a range of theories have been examined in the public health context. These include theories such as the Health Belief Model, the Theory of Planned

Behavior, interpersonal theories such as Social Cognitive Theory, stage theories such as the Transtheoretical Model, or hybrid theories such as the Health Action Process Approach. These theories outline variables on the level of the individual that explain individual health-related behavior. For example, a very parsimonious approach, the Health Belief Model, proposes the more susceptible someone feels to a health problem, the more severe they see this health problem, and the more advantages as well as the less costs of a protective behavior they perceive, the more likely they are to engage in this protective behavior. Theories such as the Health Action Process Approach (Schwarzer and Luszczynska, 2008) are more sophisticated, include several stages of behavioral preparedness with different psychosocial influence factors, and assume different phases of behavior initiation, maintenance, and recovery. Practical approaches go beyond the application of one specific model and move toward the identification of effective behavior change techniques.

However, in public health, the scope of intervention usually goes beyond the individual and therefore needs to be based on theories that go beyond the individual. For example, interventions that target health at the workplace need to account for workplace factors that interact with individual health such as an imbalance between rewards and efforts (Siegrist, 1996) or workplace demands and control (Karasek, 1979). More integrative theories such as the Reserve Capacity Model (Gallo, 2009) can help to understand how socioeconomic factors interact with individual factors in determining health. There have also been recent efforts to integrate environmental factors with individual predictors of health behaviors, for example, the interactions between environmental factors such as district-level resources and attitudes, or self-efficacy and the built environment (Carlson et al., 2012) in predicting health behaviors such as physical activity.

Theories such as Social Cognitive Theory (for an overview, see McAlister et al., 2008) assume that health-related behavior is both shaped by the individual and the social environment within which individuals live. By observing others' behavior and the results of others' behaviors, we shape our own expectations, make learning experiences, and determine our capability to change health-related behavior (social learning). Theories that operate on this level of influence on health can help to understand and (potentially) modify the effects of interpersonal networks such as families, friends, or peers on behavior.

Finally, on the level of organizations and society more broadly, theories about the functioning of social systems consider factors that impact on change of institutions, organizations, or communities. For example, the Diffusions of Innovations Theory (Oldenburg and Glanz, 2008) proposes that the degree to which innovations (such as health initiatives) permeate a social group is determined by the communication channels available, the time since the innovation and properties of the social system. Understanding these parameters can help to identify access points for interventions to achieve wide-reaching distribution.

From a practical viewpoint, however, the interaction between environmental, social, and individual influences on behavior can be very complex, so that more integrative models or frameworks that operationalize health promotion and prevention as a process through multiple levels, from individual to policy level, are often employed as tools to develop, implement, and evaluate such programs.

One such framework, the PRECEDE–PROCEED model (Green and Kreuter, 2005) outlines eight steps that allow mapping a series of measures to promote health on different levels – from the individual to policy makers. The model includes a detailed needs assessment of the health problem on a social, an epidemiological, behavioral and environmental, an educational and ecological, and an administrative and policy level. More importantly, this model also includes a framework for evaluating the impact of interventions on these different levels and thus provides an integrative framework that allows including theories for individual and organizational change on different levels. Furthermore, Intervention Mapping (Bartholomew et al., 2011) has also been developed as a very comprehensive model that identifies theory as well as theory- and evidence-based methods to promote behavior change that can be integrated into the PRECEDE–PROCEED framework. It involves the specification of a series of matrices outlining the change objectives and determinants of change on various levels (e.g., determinants of individual increases of physical activity in a specific target population need to be linked with the determinants of an organization adopting a workplace health promotion intervention based on these individual determinants of physical activity). Such integrative and multilevel models are increasingly used as comprehensive frameworks to understand the determinants of a particular health issue or behavior and to develop effective public health interventions.

Implementation and Wider Uptake of the Social and Behavioral Science Evidence Base to Improve Public Health

With the development, implementation, and evaluation of a series of major community-based cardiovascular prevention trials during the 1970s and 1980s, widespread use was made of multilevel intervention or change strategies underpinned by behavioral and social science theories and research for the first time. Importantly, these strategies did not focus exclusively on change in the individual. Instead, preventive strategies using multiple approaches were directed at the media, legislation, and the use of restrictive policies, and involved specific settings such as schools, the workplace, health-care settings, and other key groups in the community, with the aim of reducing population rates of risk behaviors, morbidity, and mortality.

The North Karelia Project in Finland (Puska et al., 1985) was initiated in response to concern that the community, at that time, had the highest risk of heart attack worldwide. Strategies included tobacco taxation and restriction, televised instruction in skills for nonsmoking and vegetable growing, and extensive organization and networking to build an education and advocacy organization. After 10 years, results indicated significant reductions in smoking, blood pressure, and cholesterol, and a 24% reduction in coronary heart disease mortality among middle-aged males. The Stanford Three Community Study (Maccoby et al., 1977) demonstrated the feasibility and effectiveness of mass media-based educational campaigns and achieved significant reductions in cholesterol

and fat intake. The Minnesota Heart Health Project (Mittelmark et al., 1986) used interventions aimed at raising public awareness of risk factors for coronary heart disease, and changing risk behaviors through education of health professionals and environmental change programs, such as grocery store and restaurant labeling.

Worksite intervention trials, such as the Working Well Trial (Sorensen et al., 1996), also utilized interventions aimed at favorably altering social and psychological factors known to influence health-related behaviors, including increased awareness of benefits, increased self-efficacy, increased social support, and reduced perception of barriers. Strategies in this setting can include promotion of nonsmoking policies, increasing the availability of healthy foods in canteens and vending machines, group education sessions, and access to exercise facilities. School-based interventions provide an established setting for reaching children, adolescents, and their families to address age-pertinent health issues such as smoking, teenage pregnancy, and substance use. Strategies have targeted social reinforcement, school food service, health-related knowledge and attitudes, local ordinances, peer leaders, and social norms.

In evaluating the effectiveness of such trials, Rose (1992) states that it is important to acknowledge the differences between clinical and more population-based approaches. Clinical approaches, while more likely to result in greater mean changes in individuals, are less significant at a population level because fewer individuals are involved. In contrast, the small mean changes achieved by population-based approaches, if applied to a large number of people, have the potential to impact much more significantly on population rates of disease and health. Furthermore, one of the difficulties in evaluating such population-based approaches is the length of time required to demonstrate changes in population rates of health outcomes. While researchers can readily measure changes in a behavioral outcome – such as the rate of smoking cessation – following a widespread and well-conducted program, the time required for such behavioral changes to impact upon long-term morbidity and mortality – such as lung cancer – is much more problematic. Nevertheless, many of the above-identified behavior-based trials demonstrate the value of social and behavioral theories and the feasibility of activating communities in the pursuit of health.

The ultimate value of this research must be determined by the extent to which the knowledge generated is widely disseminated, adopted, implemented, and maintained by 'users' and, ultimately, by its impact on systems and policy at a regional, state, and/or national level (i.e., institutionalization). While considerable effort and resources are devoted to developing effective interventions, relatively little attention has been given to developing and researching effective methods for the *diffusion and implementation* of their use. It is important to acknowledge that the availability of relevant research findings does not in itself guarantee good practice. Such knowledge transfer involves the development of formal research policies, formalized organizational structural support, appropriate and targeted funding, formal monitoring of activity, and ongoing training.

In essence, achieving the effective diffusion of innovations, both within the general community and in organizational settings, involves change, and the change principles which underpin the diffusion process are not so different to those previously identified for understanding change at the individual, organizational, or community levels. At the level of the individual, family, or small group, uptake of a health promotion innovation typically involves changes in behaviors or lifestyle practices which will either reduce risk factors or promote health. At an organizational level, such as the workplace, school, or the health-care setting, successful uptake of an innovation may require the introduction of particular programs or services, changes in policies or regulations, or changes in the roles and functions of particular personnel. At a broader community-wide or even societal level, the change process can involve the use of the media and changes in governmental policies and legislation, as well as coordination of a variety of other initiatives at the individual and the settings level.

However, in considering the principles that underpin the diffusion of innovations at a population level, further complexity arises from the need to consider change occurring at multiple levels, across many different settings, and resulting from the use of many different change strategies. This requires the application of multiple models and theories to develop frameworks with sufficient explanatory power.

Looking to the Future

It is difficult to be certain about the public health challenges that lie ahead in the twenty-first century. It is clear that in all countries, there is still a need to reduce preventable disease and premature death, reduce health inequalities, and develop sustainable public health programs. Much of the social and behavioral science research conducted with individuals is still relevant in the field of public health, as are many of the models and theories developed and tested over the past 40 years. To move to a population-based focus, we need innovative means of implementing such knowledge, and methodologies so as to increase the reach of such programs to more people, particularly the most disadvantaged individuals and sections of society.

Adopting preventive approaches to improve health, acknowledging and acting on the importance of social and environmental factors as major determinants of population health, and reducing health inequalities provides a substantial challenge to public health now and in the future. Furthermore, limited resources place an emphasis on evaluating the affordability and sustainability of public health interventions. Public health should be at the forefront of developing and researching effective intervention methods and strategies for current and future health challenges, with global sharing of information in terms of monitoring health outcomes and development of the evidence base. However, this research should not focus solely on developing strategies and testing their efficacy and effectiveness. There is an important need for research that examines larger scale implementation and diffusion of these strategies to whole communities and populations, through the innovative use of a variety of psychological, social, and environmental intervention methods, including evidence from the social and behavioral sciences.

Public Interest

Abstract

The question of public interest must be considered under four headings. First is the formal or conceptual question. This includes problems such as the meaning of public as opposed to private, self, and common interest, and the meaning of interests as distinguished from other goods and qualities. Second is the question of what substantively the public interest is. Third is the issue of how the public interest can be used as a guide for specific actions and concretely implemented. Fourth is the issue of the degree to which voters, politicians, and bureaucrats actually seek in their actions to serve public rather than private concerns.

Scholars debate the question of the public interest somewhat less than they once did, but it remains an important issue, even if "much maligned and dismissed" (King et al., 2010). As is true of other central concepts, the passage of time does not always lead to an increase in acuity, although it does lead to changes in emphasis (Friedrich, 1962; Lewin, 1991). Much that might be considered under the rubric of the public interest, moreover, continues to be discussed in terms of associated ideas such as justice, responsibility, and community (Blitz, 2005; King et al., 2010). This ambiguity complicates a topic that is itself elusive.

What Is the Public Interest, Conceptually?

The issue of the public interest is best organized under four headings. First is the formal or conceptual question. This includes problems such as the meaning of public as opposed to private, self, or common interest, and the meaning of interests as distinguished from other goods. 'Public' sometimes is taken as anything that is not private, so that regard for the public interest means any regard for interests or groups that are not strictly or exclusively one's own (Lewin, 1991). Less broadly, a public often is said to be those affected by private groups, in the sense that people who are neither labor nor management are affected by strikes. Such publics, moreover, sometimes are taken to refer to those potentially and not just actually affected as, say, any potential passenger might be inconvenienced by a strike of air traffic controllers.

Someone can, therefore, have both a private and a public interest in the same matter, and 'self' interest need not be identical to private interest. In this sense we are all members of many publics (Dewey, 1927). Often, however, the public interest is taken to be what is in the interests of 'all' of us, presumably as citizens within some boundary, although the questions of scope and authority are often curiously undiscussed. There are not many publics in this view but, finally, one public (Friedrich, 1962; Barth, 1992). The public is the group that makes law. Of course, its interests may be the sum of those of the many affected publics into which it can be divided.

Many discussions of the 'public' in these terms have in mind economic matters, or the point of view of academic economics (Friedrich, 1962). A public is seen as an affected or lawmaking group of individuals that seeks satisfaction in economically calculable terms. Publics want things that market failures cause them to receive inadequately. It is serving such publics that defines the responsibilities of professionals and of businesses 'affected with the public interest.' One strength of this conception is that since the 1950s it has brought to bear an increasingly sophisticated understanding of economically rational action, both strategic and straightforward.

There are, however, limits to this perspective. They are evident in the narrowness of the economic view of the public when it is compared to other notions of what is potentially common in common goods. For, what is common is not limited to what each independently and equally can use or enjoy, as we use markets. The common also can involve things of which we are only parts, sometimes equal or identical and sometimes not, as a face is common to its different parts or a team or family common to its members. The ties that characterize what is common, moreover, are not limited to what covers or blankets us universally, but include attaching, placing, fitting, ordering, attracting, and other links integral to images of politics from Plato through Hegel. Practical and economically based notions of the public interest will, of course, often take these distinctions for granted, but deeper exploration of the concept of the public interest cannot.

Just as 'public' is often narrower than common, so too are 'interests' conceptually different from goods more broadly conceived. Discussions of the public interest often refer to Adam Smith and, therefore, to a view of what is good as what satisfies desire in the somewhat flat, calculable, and exchangeable manner of post-Hobbesian or Lockean bourgeois life. Interests are linked to what is merely interesting or desired, not to goods as objects of passion, longing, pride, or nobility or to the character and institutions that support and direct these. Public interests are what several of us happen to desire or means to satisfaction that we generally want. Part of the conceptual task in understanding the public interest is to consider the different ways of experiencing goods so that we can grasp how interests are goods conceived in a limited manner that is linked to the premises of liberal individualism.

What Is the Public Interest, Substantively?

A second question about the public interest is what it is substantively. This issue involves both scope and content. Some scholars seek to limit questions of the public interest

 http://dx.doi.org/10.1016/B978-0-08-097086-8.93112-X

only to certain kinds of public goods. Others use it to stand for national goals, purposes, or goods more comprehensively (Long, 1991). In practice, too, speaking of the public interest generally differs from considering the public's interest in assuring the provision to all of some specific good such as telephone service.

When the scope of the public interest is limited to economic concerns, so too is the content of what is said to comprise it; for some the public interest does not even include protecting rights. To limit the concept in this way risks confusion when 'public interest' retains its broad use in practice and even in theory; to use it broadly, however, seems to involve every question of human purpose and to require some other concept to take the place of the idea used narrowly.

Just as our understanding of the public interest conceived narrowly has benefited from developments in economic understanding, so too has substantive discussion about the public interest conceived broadly undergone notable developments since the 1950s. The triumph of liberal democracies in the Cold War has directed the concerns of the left away from socialism simply to expanding the place of egalitarianism and community within liberal democracy itself. A wish among those who reject the revivified concept of natural rights to nonetheless ground the place of rights and defend them from simple utilitarian calculations has become widespread. Concern with the place of virtue and nobility in liberal democracies and, indeed, concern with these phenomena simply has been renewed (Rawls, 1971; Strauss, 1952). All these trends have enriched and re-energized discussions of the public interest.

Can the Public Interest Be Implemented?

The third question is how the public interest might be implemented concretely and used as a guide for action. Some thinkers argue that the 'public interest' is too vague to be used other than rhetorically or that it is merely a name that sums up a country's political and economic life at some moment frozen in analytical time (Friedrich, 1962). More charitably, one might concede that it means a certain level of economic satisfaction and political freedom, but that these are best reached through private and political competition, that is, when no one aims at them directly.

When we conceive the public interest broadly, however, it is not always so difficult to discern how it might guide action. Constitutions, for example, cannot be formed well without explicit attention to more than private concerns: Charles Beard's worm's eye view of the framing of the American Constitution has been debunked by more thoughtfully elevated judgments (Kesler, 2000; Mansfield, 1991). Once constitutionally secured, individual rights and liberties must be exercised individually, but steps to protect these rights publicly must be attended to explicitly by jurists, legislators, and executives. National defense is a public interest that guides specific legislative and executive action.

To say that the public good often receives explicit attention is not to say that it goes without debate, but to call it debatable is not to call it meaningless. The deliberations and result of the US constitutional convention prove the contrary. Similarly, if we take our private interest to include moral and intellectual excellence and not only economic opportunity and satisfaction we would not say that the disputability of these ends makes them pointless. On the contrary, their subtlety may make our attention to them all the more intense.

If we conceive the public interest more narrowly as assuring some equitable or safe provision and distribution of certain goods then it is again clear that the public interest can be a concrete guide. Are expanding access to communications and increasing public health served better by explicit government regulation with a defined public interest in mind of such and such a level of drug safety, health care, and access to the internet, or are they better served by discovery and application fueled largely by private desires for wealth, knowledge, and mastery, with little regulatory adjustment of the private application of resources? Is improved education secured better by unfunded parental choice, by funded choice, or by public provision or standards? Explicit attention to health, education, and responsible choice as public interests seems necessary to help secure their sufficient provision and fair distribution, if only to ward off excessive regulation and allow private efforts to flourish.

Is the Public Interest Followed?

The fourth question is whether anyone in practice pays attention to the public interest or whether private interest in fact dominates even in public matters. It is argued that the actions of voters, representatives, and bureaucrats all can be explained as attempts to enhance private goods; this analysis can be expanded to professionals, journalists, and intellectuals who do public talking, if not public business, for a living. Even if the public interest could guide us, in this view it does not.

Some research in the US and Western Europe indicates that voters do not simply or usually vote their immediately selfish economic concerns, that the behavior of representatives cannot always or primarily be explained by their wish for re-election, that bureaucrats do not always want to increase their agency's size, and that groups and individuals sometimes do seek benefits for publics from which they and their members do not receive special advantages (Lewin, 1991; Wilson, 1989). Of course, a link between private and public interest is to be expected and largely desired in liberal democratic regimes, for the responsibility we encourage in citizens and officials is meant to benefit not just others but oneself as well (Kesler, 2000).

Obviously, whether political action actually attempts to serve public interests requires continued study. Only the excessively naive would believe that unbridled devotion to a clearly conceived common good directs each and every political choice. But only the false or foolish sophisticate would believe the public interest to be as fleeting and airy as the summer snow.

Abstract

Public interest law is a branch of legal practice committed to representing traditionally underrepresented groups and interests. It has historically been associated with test case litigation designed to not merely affect the outcome of a particular dispute, but to influence public policy. Yet it has also been – and perhaps is now increasingly – focused on a broad range of legal advocacy: some before government administrative agencies and legislative bodies, and others in connection with grassroots organizing, economic development initiatives, and social movement campaigns. The defining feature of public interest law is that, unlike individual legal representation, it focuses on reshaping public policy and affects the interests of a substantial population.

Introduction

Public interest law is a branch of legal practice committed to representing traditionally unrepresented groups and interests. It went through a period of rapid growth in the United States in the 1970s and in the early decades of the twenty-first century is an important, though small component of the legal system in the US and many other countries. Public interest law has traditionally been associated with test case litigation designed to not merely affect the outcome of a particular dispute, but to influence public policy. Yet it has also been – and perhaps is now increasingly – focused on a broad range of legal advocacy: some before government administrative agencies and legislative bodies, and others in connection with grassroots organizing, economic development initiatives, and social movement campaigns.

The defining feature of public interest law is that, unlike individual legal representation, it focuses on reshaping public policy and affects the interests of a substantial population. The class action device has at times been used in such cases, although similar goals have been advanced by lawyers representing an organization or, in appropriate cases, even by representation of a single individual on a matter where substantial issues of legal principle are involved. In the classic public interest model, a lawsuit in which a doctrinal innovation is made is followed by strategic efforts to elaborate, or expand, the new principles. In addition, public interest law has sought to use legal advocacy to build policy change through legislative advocacy and to change public attitudes about social problems, as the recent campaign for same-sex marriage in the United States has illustrated (Cummings and NeJaime, 2010).

During the last third of the twentieth century, there were significant shifts in public policy in the United States in critical areas such as race relations, environmental protection, and women's rights. In each of these areas, public interest lawyers played an important role in tandem with citizen organizing and political action. When legislatures and other agencies of government were closed to citizen advocates, courts were often used to advance causes. Court decisions in public interest cases often precipitated action in administrative agencies, legislatures, and the executive branch, which would otherwise not have come about.

Antecedents

Although the name public interest law was not coined until 1969, its antecedents existed as a set of practices for much of the twentieth century. Historically, public interest law in the United States is associated with several movements, some of which were concerned with broad societal issues, others of which were more concerned with the individual's access to basic legal representation.

One important precursor of public interest law was the decades-long campaign to redress racial discrimination and racist institutional structures. In this arena, the National Association for the Advancement of Colored People's Legal Defense and Education Fund (LDEF) was the paradigm. The LDEF was established in the mid-1930s, and a brilliant group of civil rights lawyers led by Thurgood Marshall (later a Supreme Court justice) devised a strategy to bring a succession of test cases through the federal courts to the Supreme Court that would gradually undermine the legal foundations for racial segregation. The sequence of cases led to the landmark decision in 1954 of *Brown v. Board of Education*, which ended formal, legally mandated segregation in American public schools. In subsequent decades, a series of lawsuits followed to apply the principles of *Brown* in specific situations and to carry them forward into other areas where racial discrimination was practiced such as employment and housing.

Another important pillar upon which public interest law rests is the movement for freedom of expression advanced by the American Civil Liberties Union, which grew out of the National Civil Liberties Bureau's defense of antiwar advocates during the years of World War I. Also helping to build public interest law was the consumer movement, embodied in various organizations founded by Ralph Nader, and tracing its lineage back to Supreme Court Justice Louis Brandeis and progressive-era antitrust legislation. The start of the twentieth century saw the emergence of the idea that the American government had

a right, and often a duty, to regulate the marketplace and ameliorate some of the injustices of a *laissez-faire* economic structure. Brandeis developed the idea that a 'private attorney general' could go to court to enforce the law if government failed to act. This idea has remained a foundational element of contemporary public interest practice. The legal aid movement, which began in the late nineteenth century in New York as a way of providing charity-based legal representation for people too poor to pay private attorneys, also influenced public interest law. Legal aid expanded in the post–World War I period in the wake of Reginald Heber Smith's 1919 book *Justice and the Poor*. In the 1960s, as part of President Lyndon Johnson's War on Poverty, a major federally funded legal services program dramatically expanded and strengthened legal aid. With the expansion of federal antipoverty programs in the 1960s, many lawyers within legal services developed public interest law strategies and highly specialized knowledge, litigating issues such as welfare policy, health care for the poor, and the availability of subsidized housing. They used class actions and other litigation strategies to achieve important policy shifts.

Since the 1960s, public interest law has broadened its scope to include such areas as environmental law, in which public interest advocacy groups have built a framework of effective judicial precedents, federal statutes, and regulations. In the 1970s, public interest groups litigated suits that delayed the construction of the Trans-Alaska oil pipeline and forced its redesign; challenged, and eventually halted, the domestic use of the pesticide DDT; and won stricter oversight of nuclear power plants. In the following decades, public interest law organizations specializing in environmental issues have developed into large membership organizations with increasingly sophisticated technical expertise, and a range of coordinated strategies involving litigation, administrative advocacy, grassroots organizing, political advocacy, and public relations. Their efforts have been joined by other groups addressing a broad range of issues, such as gender-based and sexual orientation-based discrimination, and serving a wide range of constituencies, including immigrants, people with disabilities, children, prisoners, and many others.

The Public Interest Law Firm

Sarat and Scheingold (1998) describe public interest law as using 'legal skills to further a vision of the good society'. Most legal work is, in theory, value-neutral, and the attorney representing a fee-paying client without regard to the merits of his claim. Public interest law is, at its core, a systematic effort to bring new voices into policy formulation, and to use the law to attain certain public policy objectives, such as the abolition of legally authorized segregation or the implementation of better environmental protection. Lawyers accept lower levels of remuneration in exchange for having the freedom to pursue social goals and to represent only clients whose causes they believe have genuine merit.

Many public interest lawyers in the United States work in nonprofit public interest law firms, granted tax-exempt status by the Internal Revenue Service on the condition that they are paid a salary by the firm instead of fees by their clients, and that they take on cases broadly defined as having implications for the public good. The firms' efforts are supplemented by the work of lawyers in private firms who are willing to take on a limited number of *pro bono* cases, and by law students who receive academic credit for their work in law school clinics.

The Internal Revenue Service's recognition of the charitable status of public interest law firms has allowed foundations to channel money to these groups. Philanthropic organizations such as the Ford Foundation, the Rockefeller Brothers Fund, and the Edna McConnell Clark Foundation donated millions of dollars to public interest law organizations. Foundations were particularly important in providing seed money to the public interest movement in the 1970s. Subsequently, many of them became reluctant to fund public interest law activities, especially litigation, because of the controversy such activities engender. Nonetheless, many progressive foundations have continued to support regional organizations to provide funds for local and regional public interest law activities.

The first of the new generation of public interest law firms, and one representative of the field, is the Center for Law and Social Policy (CLASP), established in 1969. It was founded by four attorneys (including one of the authors) experienced in the distinctive legal culture of Washington, DC. They had backgrounds in corporate law practice and the executive and legislative branches of the federal government. They believed that effective legal advocacy on behalf of corporations often subverted the mechanisms of government; that the process was impoverished by the absence of effective advocacy on behalf of consumers, environmentalists, the poor, the victims of discrimination, and others' interests. They organized a bipartisan group of eminent bar members to serve as a board of directors for CLASP. Within a year, CLASP had won landmark victories in two major environmental lawsuits. Early CLASP clients included Ralph Nader, the Wilderness Society, and the American Public Health Association.

Historically, public interest law organizations have focused on issues that can be broadly defined as progressive or liberal, acting as a counterbalancing force to corporate power and serving the needs of the poor and powerless. Public interest lawyers frequently provided a counterweight to corporate advocacy. As such, it was essential that they render top-flight legal services and that they be backed up by the specialized technical expertise that was vital in many complicated cases. Public interest law thrives on both publicity and broader citizen participation. Often litigation launched on behalf of individuals or groups by public interest lawyers is one element in broad campaigns involving political lobbying, sophisticated media campaigns, and sometimes direct action.

The Evolution of Public Interest Law

Growth

Public interest law occupies a radically different place within the profession 40 years after its inception (Chen and Cummings, 2013). No longer in 'fragile alliance' with the organized bar (Scheingold and Sarat, 2004: p. 44), public interest law in the United States now enjoys the status of a stable and strongly supported occupational category within the legal profession. From an organizational perspective, the field has shown impressive expansion. Although direct

historical comparisons are not possible, the available data point to significant growth in both the number and size of public interest law groups over the movement's life span. Using survey data from 1975, Handler et al. (1978) identified 576 lawyer positions in 86 public interest law organizations nationwide (excluding legal aid organizations), yielding an average of approximately seven attorneys per group. In addition, Johnson (1974) reported that in 1972 there were 2660 lawyers in roughly 850 federally funded legal services offices (for an average of three attorneys per office). Taken together, these public interest lawyers (3236 in all) were approximately 0.7% of the total bar at the time. According to Nielsen and Albiston's 2004 survey data, there were slightly more than 1000 public interest law organizations (including legal aid organizations) with an average of 13 lawyers per group, for an estimated total of 13 715 attorneys in the field – approximately 1.3% of the total bar (Nielsen and Albiston, 2006). Although the 1975 and 2004 data are not directly comparable – and it is clear that public interest lawyers remain a tiny fraction of the overall bar – it does seem likely that significant growth has occurred, with these figures suggesting roughly a doubling of the public interest sector relative to the total bar. And this figure does not include public interest lawyers working in other sites, such as government, small firms, or clinical programs.

As the field has expanded, there appears to be more law school support for public interest students, which may promote supply – and increase competitive pressures within the field. Granfield's study (1992) of Harvard and Northeastern law students in the 1980s documented the socialization pressures that led to public interest 'drift.' Since that time, there have been new investments of resources in law schools devoted to 'nurturing' public interest law (Abel, 2002). According to The Equal Justice Works Guide to Law Schools in 2014, 21 US law schools (out of 198) reported offering public interest or public service specializations, while 35 provided public interest scholarships. Granfield's research suggests that institutional commitments to public interest law may nonetheless be overwhelmed by the dominant pedagogical style of law school and the availability of elite firm jobs for graduates. Public interest specializations are designed to counteract these influences by selecting students with public interest experience and fostering a subcommunity of ideological resistance.

In a similar sign of US law school commitment to public service, Rhode (2005) reports that one-fifth of law schools mandate pro bono or public service requirements as a condition of graduation, while half have formally administered voluntary programs. In the race to attract the best students and provide secure opportunities for summer employment, it has also become commonplace for top schools to offer summer funding for public interest jobs through some combination of law school financial support and student fundraising. Hiring processes for public interest jobs, too, have become more systematic and 'firm-like.'

A major issue affecting entry into public interest practice is quality of life. New public interest lawyers are relatively happy with their job settings, the substance of their work, and their engagement in social issues, but report sharply lower satisfaction levels when it comes to salary and opportunities for professional mobility (Dinovitzer et al., 2004). At $38 500 in 2004, average entry-level salaries of public interest lawyers were the lowest of any practice setting. Moreover, the disparity between public interest and law firm salaries has grown significantly. In the early 1970s, the ratio of private firm to public interest salaries was 1.5:1 (Komesar and Weisbrod, 1978). In 2004, the ratio of private firm (over 20 lawyers) to public interest salaries was roughly 3:1 and the ratio of big firm (over 250) to public interest salaries was 3.6:1. Law school debt has also increased – climbing sharply over the past several years – to $100 000 for private school graduates and over $60 000 for public school graduates as of 2009 (Schrag and Pruitt, 2011). The combination of stagnating salaries and rising debt would be expected to affect the supply as well as the potential quality of public interest lawyers, as those with opportunities to take high-paying jobs may do so despite a commitment to public interest practice. The development and expansion of law school Loan Repayment Assistance Programs (LRAP; and the 2007–08 enactment of federal loan forgiveness for public interest lawyers) to subsidize loan repayment for law school graduates who take low-paying public interest jobs was intended to alleviate the debt burden (and thus close the salary gap). The number of LRAPs at law schools doubled between 2000 and 2006, from 47 to 100 (Schrag and Pruitt, 2011). Fellowship programs have also played a significant role in producing public interest lawyers – at least at the elite end of the public interest bar. The Reggie program funded roughly 2000 fellows between 1967 and 1985 to enter legal services practice. The contemporary counterparts are the Skadden Fellowship and the EJW Fellowship programs. Both have been responsible for providing opportunities for elite law school graduates with demonstrated commitment to enter public interest practice by providing full salary and loan assistance.

Ideology

At its inception, the public interest law movement was explicitly a progressive one. Its 'public' was composed of those whose voices were deemed underrepresented in American politics: Blacks, women, the poor, consumers, environmentalists, and other marginalized groups. And its 'law' was mainly that of the federal judiciary, to which liberal lawyers turned to protect minority rights and promote (their version of) the collective good.

Political conservatism has reshaped the field of public interest law in three related ways: politically, organizationally, and ideologically. Politically, conservatism has transformed the 'social context' of public interest law. From an advocacy perspective, the major change has been the declining role of the federal government as the guarantor of legal rights associated with political liberalism. The most striking change has come in the judicial arena, where the struggle over the ideological composition of the federal bench has moved the weight of the judiciary toward a constitutional vision skeptical of economic regulation and minority rights. Republican control of the presidency for 7 of the 10 terms before the 2008 election of Barak Obama reversed majorities of democratically appointed judges at both the circuit and district court levels, and solidified the conservative majority on the US Supreme Court. The federal court, deemed the final arbiter of liberal claims to social justice during the civil rights period, has thus been transformed

into, at best, an unreliable ally and, at worst, a hostile enemy to be avoided.

Research suggests that liberal public interest lawyers are adapting their strategies to respond to the political realities – a trend that appears supported by the limited empirical evidence available. Although public interest groups continue to focus on filing lawsuits, Rhode (2008) reports that "it is with a more realistic vision of how they will serve long-term goals." While the mean percentage of legal work at public interest groups has remained constant since 1975, more groups are doing little or no legal work and spending more time on research, education, and outreach (Nielsen and Albiston, 2006). At the elite end of the public interest bar, there is also evidence to suggest that groups are engaged in more legislative work than in the early public interest law phase.

Organizationally, conservatism has both challenged public interest groups on the left and strengthened groups on the right. There have been well-documented attacks on liberal public interest lawyers, most notably in the 1996 the Legal Services Corporation (LSC) restrictions prohibiting lawyers in LSC-funded organizations from taking on class actions or collecting attorney's fees – thus limiting the type of cases undertaken by legal aid lawyers to routine individual service. In another example, Albiston and Nielsen found that the US Supreme Court's 2001 decision in *Buckhannon v. West Virginia*, which repealed the 'catalyst theory' for attorney's fee awards, has discouraged public interest groups from undertaking civil rights enforcement actions, particularly when the remedies are limited to injunctive relief. On the right, as Southworth (2008) has demonstrated, conservative groups have also contested public interest law from 'inside' the movement by establishing a countervailing set of legal organizations dedicated to advancing a right-wing political agenda under the rubric of serving the public interest. As a result, on the most contentious sociopolitical issues of the day, liberal public interest groups – standing for economic regulation, redistributive social welfare, the separation of church and state, the rights of criminal defendants, and protections for minority groups – have found themselves pitted against their conservative counterparts advocating a mirror-image agenda – free markets, small government, a prominent role for religion in public life, law and order, and an end to affirmative action.

Funding

Public interest law organizations were catalyzed in the 1970s by an infusion of funding from the Ford Foundation and other philanthropic institutions. In the early phase of public interest law, it was foundation funding that constituted the most significant source at over 40% of total income as of 1975. Recent research suggests that foundations play a less significant – though still important – funding role. In their survey of public interest law organizations, Nielsen and Albiston (2006) reported that foundation funding had decreased to 21% of total income by 2004, while state and local funding had increased to 28%. However, part of this reported decrease may be due to the fact that the study included legal aid organizations relatively more dependent on governmental funds. Rhode, in contrast, found that for the prominent public interest groups that she surveyed, foundation funding constituted an average of 37% of organizational budgets, while government funds represented only 1%. In addition, Rhode (2008) found that individual donations represented an average of 28% of total income, with corporate donations constituting another 14%. This suggests that elite public interest groups may be as dependent – or even more dependent – on private individuals and corporations for financial support (42% of total income) than foundations. What does this mean for organizational governance and programmatic content? One interpretation might be that such private donations reflect significant law firm financial involvement in these organizations. And one would expect such involvement to be accompanied by law firm representation on the groups' boards of directors. How far such financial relationships extend and how much they influence organizational policy are the questions that have troubled observers of public interest law since Bell (1976) charged the Legal Defense Fund with 'serving two masters' in its pursuit of school desegregation. If it is the case that law firms and other private sector actors are exercising more financial control over public interest law organizations, business considerations may compete with ideology in shaping their dockets.

Perhaps no public interest institution has been as politicized as the legal services program, which began in 1965 with federal funding as its primary source. The political backlash to its liberal agenda resulted in efforts to privatize the program and brought significant federal budget cuts that forced legal services offices to rely more heavily on foundations, law firms, individuals, and state and local government funding. In 1981, LSC mandated that its grantees make a 'substantial amount' of funds available for Private Attorney Involvement (PAI). Although the PAI program resulted in some direct payments to private practitioners, its major effect was to stimulate the expansion of programs designed to recruit, train, and connect pro bono volunteers with low-income clients. Spurred by the PAI mandate, the number of pro bono programs rose from about 50 in 1980 to over 500 in 1985. By the early 1990s, there were approximately 900 pro bono programs, and in 2004 there were roughly 1000. In terms of funding, LSC financial support declined just under 50% (in real terms) between 1980 and 2009. Overall legal services funding has held relatively steady, but has been diversified. As of 2005, LSC funds constituted only about one-third of the total legal services budget in the United States, with state and local government funds contributing about one-third, Interest on Lawyers Trust Accounts (IOLTA) about 10%, foundations about 7%, and private lawyer contributions roughly 4% (Houseman, 2005).

The constraints are much clearer in the context of big firm pro bono, which has grown in institutional scope and constitutes an important vehicle for delivering legal services to the poor. Pro bono's institutional ascendance occurred against the backdrop of several trends (Cummings, 2004): declining federal support for legal aid, which prompted the organized bar to promote pro bono as a complement to state-sponsored legal aid; the growth of big firms, which permitted the large-scale mobilization of pro bono resources through centralized planning; the advent of law firm rankings, which focused attention on pro bono as a recruitment strategy; and pressure from attorneys to give back in the face of law firm financial success. As pro bono has become institutionalized, it has also emerged as a significant component of US civil legal assistance.

Sandefur (2004) reports that, in 1997, lawyer pro bono work constituted "more than one-quarter of the full-time equivalent lawyer staff providing civil legal assistance." In addition, pro bono cocounseling is commonplace in public interest impact litigation, with Rhode (2008) finding that "almost all of the large national organizations relied heavily on pro bono counsel for impact litigation, and involved them in at least half of their major cases."

From a quality perspective, the rise of pro bono means that there are more attorneys working on public interest cases episodically – as part-time relief from their billable client work. This has implications for commitment and expertise. Some public interest attorneys complain about the need to closely monitor the quality of the work of pro bono volunteers, who at times are not closely supervised and are pulled away from pro bono work by their billable commitments. In addition, nonexpert pro bono lawyers may miss opportunities for connecting cases to broader law reform or political organizing efforts, and may be less likely to take risks to advance larger-scale social change agendas. From the perspective of institutional design, increased reliance on pro bono for the delivery of legal services to the poor may mean that certain categories of cases are less likely to receive attention. Positional conflicts and other business constraints make big firms reluctant to take on cases that strike at the heart of their business clients' interests. Thus, labor and employment law cases are less likely to receive significant support from firms that regularly defend business clients (Cummings and Rhode, 2010). Legal services groups may, in turn, organize their in-house programs around their appeal to private firm volunteers who will ultimately help staff the cases. Similar business constraints affect the ability of public interest groups to find pro bono counsel in impact cases against corporate defendants.

When public interest groups are unable to find big firm cocounsel in impact cases, they frequently turn to small plaintiff-side firms, for which the motivation is not 'giving back' through pro bono service, but rather the opportunity to collect attorney's fees. These 'private' public interest firms have been held out as an alternative site for 'doing well' and 'doing good,' allowing lawyers to take on large-scale social change litigation that nonprofit groups cannot because of resource limits – and big firm pro bono programs will not because of business conflicts – while also addressing other deficits associated with NGO practice, such as low salaries, lack of training, and high turnover. There are no systematic data on these firms, but the available evidence suggests that they have grown in number. Handler and his colleagues estimated that there were 66 'mixed' private public interest law firms in the mid-1970s. Cummings' 2012 compilation of private public interest law firms, drawn from lists in which private lawyers are identified as practicing in the public interest, put the number at over 600 (Cummings, 2012). Although this recent list includes firms engaged in activities such as securities and mass tort litigation, the majority are firms that undertake civil rights, human rights, and environmental litigation that have analogues in the NGO sector. Some private public interest firms only work on cause-oriented cases, while others supplement their public interest docket with cases taken on solely to generate fees.

The law school clinic constitutes another important (and underexplored) site of public interest practice – embedded within legal academia – that is characterized by distinct lawyering trade-offs. The clinical movement, which began in tandem with public interest law in the 1970s when Ford granted over $10 million to the Council on Legal Education for Professional Responsibility to promote clinical education, occupies a paradoxical space within law schools: radically institutionalized and yet often marginalized. Its institutional presence is powerful: In 1999, the Association of American Law Schools (AALS) Section on Clinical Legal Education's database showed 183 law schools with clinics staffed by over 1700 clinicians – 80% of whom reported teaching in live-client clinics. Despite these numbers, lower institutional status is a pervasive complaint among clinicians, who regularly do not enjoy the security and prestige of academic tenure and its attendant benefits.

In line with its original mission of client service, law school clinics now constitute a significant force in public interest law, yet we know very little about how clinics select cases, what trade-offs they face, and how their work relates to that of the broader NGO community. There are some obvious and well-documented limitations. Clinicians must select cases based in part on pedagogical value and – as high-profile cases of political backlash against environmental clinics at Tulane and Maryland for challenging industry pollution – the representation of progressive clients or causes may place clinical programs in political (and financial) risk.

Globalization

Public interest law, like its private sector counterpart, has also experienced the impact of global forces. This has been evident in two directions: from the outside-in, with the influence of globalization on US-based public interest practice, and from the inside-out, with the interaction between US public interest law models and legal activism around the world.

Within the United States, global interdependence has produced a greater degree of internationalization within the domestic public interest law field (Cummings, 2008). There have been three key transnational processes – immigration, market integration, and human rights – that have influenced US practice. With respect to immigration, since the 1980s there has been a quantitative increase in migration to the United States combined with a qualitative change in both its pattern (more geographically dispersed) and composition (more undocumented entrants). These changes have redefined immigrant advocacy, transforming it from an ancillary part of public interest practice into a distinctive field. Significantly, the influx of undocumented immigrants seeking employment in the exploitative low-wage sector has focused public interest resources on enforcing legal protections in the workplace, leading to the development of new organizational investments promoting 'immigrant worker rights'.

As immigration has brought market integration home, the outflow of US corporations in search of investment opportunities and low-cost production locales has extended open market policies to developing countries abroad. Within these new arenas of US economic activity, the main focus of public interest law has become upgrading systems of legal governance and regulatory enforcement outside of US borders. This has involved advocating new theories of US jurisdiction under the Alien Tort Statute; entering new venues of global economic

governance, such as the NAFTA system and the WTO; and building alliances with new partners, both transnational activist networks challenging market integration from below, and governmental and philanthropic institutions promoting the rule of law from above.

Domestic practice has also been influenced by the movement to 'bring human rights home'. Whereas the international human rights system promoted in the Cold War era was, in part, a way to export American-style public interest law to activists in foreign countries resisting authoritarian regimes, the US human rights movement represents an effort by public interest lawyers to import the very norms and methods built through international struggle to contest what they view as the erosion of domestic legal standards resulting from new American policy imperatives: market integration, conservatism, and the War on Terror. Accordingly, there have been significant efforts by mainstream public interest law groups to deploy human rights strategies to advance domestic agendas in the areas of criminal justice, immigrant rights, women rights, worker rights, and the environment.

Globalization has therefore influenced what public interest lawyers do inside the US legal system (which clients they represent and which causes they pursue) as well as what types of activities they undertake outside of American borders (which international venues they enter and which networks they support). From a tactical perspective, lawyering within the international arena embraces a broad range of nontraditional techniques such as lobbying, reporting, and organizing. It also operates across institutional contexts, moving from US courts to institutional venues – like the UN and Inter-American Commission on Human Rights – where lawyers think that they can amplify their claims and have political impact.

These global trends highlight the reversals of fortune, strategic adaptations, and deep tensions that characterize the American public interest movement in the contemporary era. The international turn is itself a product of domestic political realignment: Inside the United States, the liberal public interest law movement, built upon a symbiotic relationship with the federal government, has recently found itself in opposition to the main levers of federal power. It has, therefore, looked outside US borders – not just for legal resources but also for connections with international struggles – to infuse it with a renewed sense of movement energy and political mission. And it is there that US lawyers have found new political allies, as well as opportunities to engage in large-scale reforms that seem only a dim possibility at home. Particularly on issues of labor rights and environmental justice, US lawyers have found global partners eager to assert social standards within the regime of free trade. US lawyers have similarly invested in rule-of-law reforms in developing countries, not out of an impulse to remake the world in the American image, but rather drawn by the lure of enormous possibilities for profound legal and political change. Back at home, lawyers have also tapped into international movements to promote domestic reforms, taking up the banner of immigrant rights and enlisting the legal and rhetorical power of human rights in the service of domestic causes. In contrast to the self-confident insularity of public interest law during its early phase, these movements suggest that US lawyers now perceive that the rest of the world has political lessons to teach and legal models to emulate.

When one looks outside of the United States, the questions for public interest law are different. Key issues concern why public interest law is developing abroad and the degree to which foreign public interest law resembles – or resists – US models. With respect to the spread of public interest law, three developments are important: (1) the rise of the 'new' law and development movement beginning in the 1980s, which has promoted legal aid, clinical education, and pro bono as part of a broader set of market-friendly rule-of-law reforms supported by international financial institutions like the World Bank and IMF, as well as foundations like Ford and the Open Society Institute; (2) the emergence of constitutional democracies in places like Central and Eastern Europe, which provide new opportunities to use domestic courts to advance political ends, thus allowing activists to shift away from prior reliance on the human rights system; and (3) the development of organic movements to resist neoliberal globalization through the deployment of domestic and international law in coordination with indigenous organizing groups. Scholars are beginning to focus on the shape and meaning of this advocacy and its relation to the US model of public interest law. One question concerns the degree to which legal organizations abroad receive external funding and technical assistance that may connect them to public interest networks in the global North. Such foreign influence shapes the types of cases brought and strategies deployed. On the other hand, foreign public interest law systems must adapt to local legal, political, and professional environments, which create distinct advocacy opportunities and constraints. Because these hybrid systems combine elements of the global and local, there are inevitable struggles over authorship and power, with resistance to the notion of outside intervention, even while it leaves a distinctive imprint. As the interaction between foreign transmission and local adaptation plays out, global public interest lawyers will play leading roles in their own countries' movements for democratic reform in the global era – providing new perspectives on the evolving role of law in social change across a diverse range of political and economic systems.

Conclusion

Public interest law is an assertion of a commitment within the justice system to fairness, open process, and diversity of viewpoints. In response to the challenges the movement has faced over the past 25 years, particularly more conservative courts, many public interest lawyers have developed a range of alternate strategies: working more directly in the legislative and administrative processes; filing suits in state courts; and relying more heavily on citizen actions.

Despite these challenges, public interest law in the United States – and beyond – has continued to thrive, affecting policy decisions and providing a measure of balance in the legal system. There are generally more law school graduates seeking public interest law work than there are jobs; and there are many situations in which effective public interest advocacy, were it available, would lead to better policy outcomes. Additional efforts to build the field are thus still necessary. The development of public interest law in other countries holds significant

promise for fair processes and broader public participation in critical policy decisions ranging from environmental protection to the protection of racial minorities. Globalization creates new needs and opportunities for public interest lawyers to function in transnational settings.

Public Opinion: Social Attitudes

Abstract

Public opinion and social attitudes are broadly defined as the expression of beliefs, ideology, and sentiment within a citizenry with regard to the conduct of human affairs. The concept of public opinion arose as a consequence of the rise of democracy, premised on the notion that government should rule with the consent of the governed. Methods for collecting and analyzing data on public opinion based on survey samples were first developed in the US and Europe and are now used in most countries throughout the world. Within the field of survey research, the scientific study of public opinion has emerged as a specialized area of research that is done by sociologists, psychologists, political scientists, and market researchers. In the late 1960s, political scientists in the US were surprised to find that very few people base their political opinions and vote choices on a coherent system of beliefs. They also found that large percentages of respondents seemed to switch their opinions when asked the same question at different points in time. This instability and apparent lack of ideological consistency poses serious challenges for the theory of government by democracy. Subsequent research has shown that most people's opinions are influenced by family socialization and education and are often based on perceptions of various social groups. Researchers also study the limitations of the methods and techniques used to measure public opinion in order to minimize biases that cause researchers to misinterpret their findings. Unlike the patterns of instability observed in individual opinions, public opinion at the aggregate level appears much more stable and consistent over time. Research on long-term trends in aggregate opinion has also shown that government does indeed respond to citizen preferences, but there is evidence to suggest that it has become more responsive (at least in the US) to the preferences of affluent citizens. Due to the globalization of the survey research industry, social scientists now have access to public opinion data from the vast majority of countries throughout the world.

Public opinion and social attitudes are broadly defined as the expression of beliefs, ideology, and sentiments within a citizenry with regard to the conduct of human affairs. Opinions are usually understood as an expression of underlying attitudes and sentiments, which tend to remain stable over time while opinions can change more rapidly depending on public events or exposure to new information. Social attitudes are more closely tied to widely shared human values, namely our most basic and important beliefs about human life and social order. Opinions are assessments of particular people, events, or policies as they are understood through the lenses of our basic social attitudes or ideologies. While most people generally agree on and share basic core values in a society, opinions about specific areas of life can vary widely from person to person and within individuals over the course of the life span.

Opinions are generally understood to be a result of life experiences, exposure to information, peer pressure, and other forms of social influence. Opinions vary widely in terms of substantive focus and in terms of their importance to each person. Thus, in one dimension, opinions differ in their *valence* (e.g., favor or oppose laws restricting gun ownership) and, in a separate dimension, in their *intensity* (e.g., strongly care or do not care at all about this issue). This means that while many people may share the same opinion about an issue, they may, at the same time, disagree about the importance of that issue (Petty and Krosnick, 2014). Collective action or social movements occur when individuals sharing the same opinion on an issue and a sense of urgency about the importance of that issue come together to form a group intent on changing laws, policies, or social norms. In more extreme cases, collective action driven by shifts in public opinion can result in rebellions or social revolutions (Olson and Olson, 2009).

Opinions are distinct from perceptions, which are based on observations of factual reality and can be judged as either correct or incorrect. By contrast, opinions cannot be judged as correct or incorrect: they are the result of moral or esthetic judgments. They pertain to matters of right and wrong or personal taste that are typically thought of as subjective. Opinions are part of the sphere of cognition in which individuals are free to think and judge as they wish, although the public expression of opinions may be more or less tightly controlled by various social institutions.

Historically speaking, the concept of public opinion arose as a consequence of the rise of democracy. Inherent in the principle that government should rule with the consent of the governed is the notion that government must understand and respond to the needs and aspirations of its citizens. Throughout most of human history, the exercise of power in human affairs paid little or no heed to the opinions of ordinary people. However, with the rise of the modern state and the concept of citizenship, rulers of both democratic and nondemocratic states have understood that citizens are capable of expressing their collective will in a variety of ways that may support or threaten the operations of government. This possibility is implied in the classic definition of public opinion offered by the political scientist V.O. Key (1961: 14) as the "opinions held by private persons which governments find it prudent to heed."

One of the earliest and most important studies of public opinion was first published in 1922 by journalist Walter Lippmann. In his book, Public Opinion, Lippmann argued that the complexities of modern life make it impossible for human beings to pay attention to more than just a fraction of what goes on in their environments. To cope with these complex environments and the unseen realities outside of their local

communities, people create simplified mental images of the world based on stereotypes. In forming opinions, people draw on these simplistic stereotypes to make sense of the world and events happening beyond their immediate grasp. These stereotypes are resistant to contradictory information, but at the same time vulnerable to manipulation by skilled politicians and newspaper editors. As a reporter during World War I, Lippmann saw firsthand the myriad ways that newspaper accounts were manipulated by military and political leaders to suit their own purposes. He also understood that the business of selling newspapers was based on maximizing circulation and advertising revenues, and not necessarily on delivering relevant facts in an objective and comprehensive way. By virtue of being profit-driven enterprises, newspapers are more likely to cater to their readers' stereotypes rather than challenging them. Lippmann was prescient in understanding the way most people think about politics and world affairs and the way news media play a crucial role in shaping public opinion.

> Thus the environment with which our public opinions deal is refracted in many ways, by censorship and privacy at the source, by physical and social barriers at the other end, by scanty attention, by the poverty of language, by distraction, by unconscious constellations of feeling, by wear and tear, violence, monotony. These limitations upon our access to that environment combine with the obscurity and complexity of the facts themselves to thwart clearness and justice of perception, to substitute misleading fictions for workable ideas, and to deprive us of adequate checks upon those who consciously strive to mislead.

The Scientific Study of Public Opinion

The measurement of public opinion is accomplished through opinion polls or social surveys. A poll or a survey is a systematic effort to collect information about opinions, perceptions, behaviors, or intentions among a random sample of people that is more or less representative of a larger population. While polls and surveys are a seemingly ubiquitous feature of modern life, the techniques for measuring public opinion took many years to develop. The methods used by researchers to conduct a survey or poll evolved over a 100 year period that began with the founding of professional statistical societies in Great Britain and the US in the 1830s and culminated in the first use of modern sampling methods in nationwide surveys of employment and unemployment during the Great Depression of the 1930s. During this time the techniques for creating representative samples were developed by a group of statisticians and social scientists from many different countries, including Anders Kiaer, a statistician who conducted numerous experiments with Norwegian census data in the 1890s, and Jerzy Neyman, a Polish statistician who provided the mathematical foundation for modern sampling techniques based on classical theories of probability (Converse, 1987: 41–45). Opinion polling and market research has grown into a sizable worldwide industry that employs thousands of survey researchers, interviewers, and statisticians.

Surveys and polls are now used throughout the modern world as efficient and cost-effective methods for gathering data on public opinion, but also for collecting many kinds of information needed for the normal operations of government and industry. Within the field of survey research, the scientific study of social attitudes and public opinion has emerged as a specialized area of study that includes research done by sociologists, psychologists, political scientists, and market researchers. Their data come from interviews conducted with large numbers of survey respondents in many countries around the world. These interviews are done in person, over the telephone, by mail using printed questionnaires, or over the Internet using online questionnaires. In addition to surveys and polls, researchers who study public opinion also use observations and data gathered from controlled laboratory experiments, focus groups, observational studies, and the analysis of media content such as newspaper articles and radio and television broadcasts. These researchers study the factors that influence public opinion as well as processes of social change that are driven by shifts in public opinion.

One of the first systematic, large scale efforts to study public opinion in the United States was carried out by Phillip Converse (1964), a political scientist at the University of Michigan. Converse analyzed national survey data collected from election studies in 1956, 1958, and 1960. One important feature of Converse's research was that while each of the samples were nationally representative, each one also included sample members who were interviewed at all three points in time using the same set of survey questions. This innovative design feature enabled Converse to measure change in *aggregate* opinion over the 4 year period of the study, as well as change within *individual* opinions during the same period. At the time of the study, most social scientists like Converse assumed that people generally based their opinions on a basic set of core values or social attitudes in a logically coherent way. They further assumed that most individuals maintain relatively stable opinions and attitudes over time. However, for the most part, both assumptions turned out to be wrong.

Using responses from a wide range of policy-related survey questions as well as detailed explanations for their opinions and vote choices, Converse divided the mass electorate into five different categories, configured as a pyramid, with the most highly educated and attentive voters at the top of the pyramid, moderately interested and lower educated voters near the middle, and the least interested and least educated citizens at the bottom. Converse designated the elite group at the top as ideologues, namely people who rely on clear and consistent principles (e.g., liberal vs conservative, prolabor vs probusiness, etc.) in deciding how to vote or respond to questions about their opinions on policy issues. Just below this level was a group Converse called near-ideologues – people who mention any kind of evaluative dimension in their orientation to politics, but rely on that dimension less often than the ideologues. In the third level, Converse placed respondents who do not rely on any apparent evaluative dimension, but instead explain their thinking about candidates and issues in terms of the impact of politics on various social groups. People at this level tend to see politics as the interplay between competing interest groups, so that their political opinions derive largely from their own sense of group membership and their perceptions of which groups have more power and which deserve more help. Below this group are people who talk about some policy considerations in explaining their vote and policy

preferences, but apply those considerations in a haphazard way. The last group comprises people whose views and vote choices reflect neither any kind of structured ideas or principles nor any reference to competing social interests.

When Converse sorted his survey respondents into these five categories, he found that fewer than 3% of the total sample fell into the first category (ideologues) and only 9% fell into the second category (near-ideologues). Slightly more than 40% fell into the interest group category (level 3) and the rest (almost half the sample!) were found to have little or no coherent ideological underpinnings associated with their opinions or vote choices. Thus, it was not surprising to find that many sample members also gave entirely different answers in 1958 and again in 1960 to the same set of policy questions they had been asked two years earlier. Converse noted with great concern that while opinions at the aggregate level appear to be relatively stable over time, that stability masks a great deal of instability that seems to fluctuate in an almost quasirandom manner in the minds of many individual voters. The results of his study indicated that "large portions of the electorate do not have meaningful beliefs, even on issues that have formed the basis for intense political controversy among elites for substantial periods of time" (1964: 245). Beyond giving credence to Lippmann's pessimistic view of public opinion, Converse's findings cast a long shadow over prevailing assumptions about the need for an active, well-informed and thoughtful electorate for the success of government by democracy. In fact, much of the research that has been done in the field of political science for the past 50 years can be understood as attempts to address the implications of Converse's research.

It is important to consider whether some of the incoherence and long-term instability that Converse found to be characteristic of most people's belief systems is due to limitations in the methods used to collect data on opinions. Incoherent or unstable responses are sometimes the result of poorly designed questionnaires, biases in the way questions are worded, or measurement errors related to the interview process itself. Researchers have documented a 'social desirability' bias that occurs when respondents seek to avoid presenting themselves in a negative light, and withhold from expressing opinions that might be perceived as negative (Tourangeau and Yan, 2007). This even extends to a desire to avoid appearing ignorant on issues about which the respondent has limited knowledge or no knowledge at all. An experiment by Bishop et al. (1986) showed that when asked questions about a policy proposal that was entirely fictitious, significant numbers of respondents offered favorable or unfavorable opinions when the question did not include the option of answering with a 'do not know' response. Similar kinds of experiments have demonstrated that responses to questions can be significantly altered by the use of open-ended responses vs lists of closed-ended responses; by differences in the way scale values are labeled (e.g., 0 to 10 vs −5 to +5); by differences in the end points of ordinal response categories; and by changes in the order in which questions are presented (Schwarz, 1999). Response biases have also been observed as a result of using different modes of interviewing (e.g., telephone vs in person) (Holbrook et al., 2003).

Measurement error may also result from the use of simplistic questions to gauge opinion on complex issues. Some researchers claim that Converse's methods do not adequately capture the complex process by which core values contribute to the expression of specific policy preferences. Achen (1975) argues that much of the response instability that Converse claims to detect can be attributed to vagueness in the survey questions themselves. His reanalysis of Converse's data shows that response variability over time is uncorrelated with education, income, and occupation – a strong indication that even sophisticated respondents had trouble interpreting the survey questions that showed the most response variability over time. In this way, measurement error obscures the process by which core beliefs inform opinion in a meaningful way. To better understand this process, Zaller (1992) proposes a model of survey response in which core beliefs and predispositions act as filters or gatekeepers for information flowing through our political environments. Core values affect our receptiveness to ideas and information and constrain the process through which we evaluate information and decide what to store in memory. When asked to express an opinion in response to a question, respondents call to mind a range of relevant facts, ideas, and experiences drawn from memory, and 'average' across the most salient considerations in deciding how to answer a question. Seen from this perspective, response instability does not indicate the absence of coherent core beliefs, but instead indicates the limitations inherent in the typical question and answer format used in most opinion polls.

Factors That Shape Individual Opinions

If, for most people, attitudes and opinions are not grounded in any logical, coherent way on underlying belief systems or ideologies, what then determines their attitudes and opinions? Most research on the factors that shape an individual's political opinions point to the importance of family socialization, group identity and prejudice, and the effects of education. There is even some evidence to support the notion that genetics may play a role in determining one's political outlook. Other research has examined the extent to which people base their opinions on social class or self-interest.

In reaction to the rise of Nazi Germany and the events of World War II, many psychologists and social scientists were concerned about the potential for social institutions such as the family to raise children with strong prejudices against people different from themselves. Those prejudices were part of a set of traits that became known as the 'authoritarian personality' (Adorno et al., 1950). Children reared in family environments that cultivated this type of personality were seen as strictly obedient to authority and intolerant of social groups other than their own. This was seen as an important factor in understanding anti-Semitism and other forms of prejudice. Later, during the civil rights movements of the 1960s, many researchers who studied social attitudes about race and racial equality focused less on personality traits and more on social learning processes and the role of parents in transmitting attitudes of racial prejudice to their children (Allport, 1954; Levy et al., 2010). In terms of political attitudes more generally, recent research has shown that under certain circumstances, parents exert a significant influence on the political views of their children. Using longitudinal data from three generations

of parents and children, Jennings et al. (2009) find that children are most likely to adopt parents' political orientations and opinions when parents have a greater interest in politics, provide consistent cues to their children over time and share the same views as their spouses. The effect of parent–child transmission is particularly strong when it comes to affect laden issues such as party identification, vote choice, religiosity, opinion on school prayer, and racial attitudes. This effect of parental influence holds up, though its impact is somewhat diminished, even when controlling for contextual factors such as parents' education and income, school environment, and local economic conditions. Additional evidence suggests that the timing of parental influences is unclear, with some researchers arguing that parental impacts are strongest in early childhood and others claiming that parental influence is equally or more important during adolescence (Sears and Funk, 1999).

More recent research indicates that the link between parent–child political views may occur as a result of biological or genetic influences. Using survey data collected from thousands of twins born in the US and in Australia, Alford et al. (2005) compare differences in attitudinal measures on a wide range of political issues among both identical (monozygotic) and fraternal (dizygotic) twins. They find that correlations on attitude measures are significantly stronger for identical twins when compared with correlations for fraternal twins, and this remains true even when accounting for whether or not both types of twins shared the same family environment during childhood. Although this work has been criticized for inadequately testing its assumptions about the equivalence of the environments in which twins are being raised (for example, see Beckwith and Morris, 2008), the strengths of the findings, coupled with weak but suggestive evidence on the mechanisms through which familial and environmental influences actually operate, mean that genetic backgrounds, or at least the interaction of genetics and environment, may be a significant factor in understanding the role of parental influence on attitudes and opinions.

Converse's observation that people are much more likely to think about politics in terms of interest groups than in terms of a coherent belief system helped lay the groundwork for research on the effects of ethnocentrism and its role in the formation of political identities. This view can be seen as a more generalized application of the basic ideas behind research on the authoritarian personality – beyond simply creating negative stereotypes of certain groups (such as Jews or Blacks), reference group theory, as applied in political analysis, assumes that most people see the world as composed of many different kinds of groups, some of which they view negatively and some of which they view positively (Merton and Kitt, 1950; Fiske, 1998). In addition, individuals may see themselves as members of several different groups at the same time (Catholic, working class, white, immigrant, etc.) (Tajfel, 2010). This leads to the question of whether and how often attitudes and opinions can be understood as manifestations of underlying group identities and the stereotypes people hold about groups other than their own. In reviewing past research on this idea, Kinder (2003: 18) argues that "[g]roup sentiment is not the only thing driving opinion in… various policy disputes, but it is always present, and of all the diverse ingredients that make up opinion, it is often the most powerful."

Ironically, some research has shown that higher levels of education do not always serve as an antidote to the prejudices that inform many people's thinking about politics. Stouffer (1955) was one of the first American researchers to develop measures of political tolerance and to provide evidence that education was positively associated with higher levels of tolerance for nonconformist groups. Bobo and Licari (1989) use data from the 1984 General Social Survey to show that education has a positive, independent effect on people's willingness to tolerate freedom of expression for extremist political groups. This was true even among respondents who had a negative view of those groups. Gibson (2013) finds a similar independent effect of education on political tolerance using more recent data from five national surveys conducted between 2007 and 2011. Thus, while the evidence suggests that education makes people more tolerant of various social and political groups, there is not much evidence to support Converse's original assumption that more highly educated people are less likely to think about politics in terms of racial or ethnic stereotypes (Kinder, 2003: 38).

Marxist theories of public opinion view it as an accommodation to or outgrowth of the system of control over a society's material and productive resources. People in capitalist societies may have many opinions about what policies or laws are in their best interest, but Marxist theorists assert that people's real interest lies in understanding their true relationship to the means of production – all other interests are subordinate. Thus, the only opinions that matter are those concerned with understanding and opposing the oppressive power structures that characterize life in capitalist societies. According to Marxists, people often misperceive their 'true' interests and develop 'false' beliefs (such as religion) that mask the true source of their oppression. Marxists refer to such beliefs as a form of 'false consciousness' (Rosen, 1996). This concept is premised on the idea that what is in one's best interest can be determined objectively and is not simply a matter of subjective preference (Mansbridge, 1983).

Given the capacity of democratic governments to respond to working class demands and the absence of revolutions in modern capitalist societies, Marxist theories of public opinion have not enjoyed much popularity. Critics have also pointed to the difficulty of identifying and prioritizing objective interests in modern, affluent societies (Bartels, 1996). Nevertheless, some scholars have studied instances in which people vote and express opinions that seem directly contrary to their own economic interests. Thomas Frank (2004), for example, looks at the evolution of the conservative movement throughout rural Mid-Western states to try to explain how economic issues were supplanted by cultural and symbolic issues in the minds of many voters. In his book *What's the Matter with Kansas?* Frank argues that economic conservatives in America have exploited 'culture war' issues such as abortion, school prayer, and gay rights to lure white working class voters away from their long-standing tradition of supporting labor unions, progressive taxation, and protectionist trade policies – issues that directly impact their income and employment. In another study, Bartels (2009) examines the campaign to eliminate the federal estate tax in the US. Although the tax itself affected only a very small

percentage of the nation's wealthiest families, many low- and middle-income voters expressed strong opposition to the tax even though its elimination would cause a shortfall in government revenues that would inevitably impact all taxpayers. These studies show that material interests are just one of many factors that influence public opinion.

Factors That Shape Aggregate-Level Opinion

In looking at patterns of change and stability in public opinion over time, Page and Shapiro (1992) claim that patterns of response instability that Converse and other researchers observe in individuals has limited relevance to patterns observed for the population as a whole. In contrast to individual opinion, public opinion at the aggregate level has been, for most issues, relatively stable over time. Page and Shapiro argue that even if individual response variability has a significant random component, the net result of aggregating data across many individuals is to cancel out any bias that might result from random variation in individual responses. Thus, the authors argue, while individuals may not always appear rational in their policy choices, the American public as a whole has, for the most part, been stable and consistent in its policy preferences. Page and Shapiro use data compiled from thousands of national opinion surveys conducted in the US between 1935 and 1990 to demonstrate that significant, large-scale shifts in the policy preferences of the public as a whole are relatively rare. Although major changes have occurred on issues such as civil rights, women's rights, civil liberties, the Vietnam War, and the use of nuclear power, opinions on most other issues show only moderate or negligible long-term change.

In a similar analysis of polling data, Stimson (2004) also finds long-term steady growth in the acceptance of equal rights for racial minorities, for women, and, more recently, for homosexuals. In each of these issue domains, laws and government policy changed as a result of clear shifts in public preferences. The long-term trend on nearly all other issues (including gun control, welfare spending, taxes, the environment, crime, and health care) is a pattern that fluctuates over time. Stimson argues that these fluctuations in public preference build up gradually in the years before major elections and presage subsequent shifts in political party dominance, in particular, dominance of the White House. Stimson also speculates that these fluctuations are consistent with movements of public opinion that signal changes in the public's demand for more or less spending in certain program areas. Earlier research by Wlezien (1995) finds evidence that changes in appropriations for national defense are preceded by changes in public opinion on whether the government should be spending more or less on defense. Wlezien argues public opinion in this case functions much like a thermostat, with elected officials responding to demands for increased spending and then opinion moderating as those demands are met.

Public Opinion as a Social Force

These findings raise the question of how much elected officials are aware of public opinion and how much it influences their actions. Page and Shapiro (1983) argue that aggregate-level trends in public opinion data provide clear evidence that government policy changes in response to major shifts in citizen preferences. But aggregate-level data are of limited value in understanding how government officials translate signals from voters into concrete political agenda. In a study of the ways that legislative staffers, journalists, and interest group leaders interpret and react to public opinion, Herbst (1998) finds that elected officials want to know not just what percent of citizens favor a certain policy, but how *important* that policy is to them. Opinion polls typically fail to convey how much an issue really matters to voters because they usually lack measures of attitude strength. Polls give equal weight to voters who care passionately about an issue and those who do not. For politicians, *intensity* of opinion matters as much as its *valence*. Herbst finds that most politicians use an operative definition of public opinion that takes account of more than just numbers from polls and surveys. Elected officials depend on interest group leaders, lobbyists, reporters, newspaper editorials, constituent communications, and networks of local party officials for clues about the issues that concern voters and how much they are concerned. As such, data from polls and surveys reveal only one dimension of what elected officials regard as a multifaceted phenomenon.

This leads to the question of whether elected officials treat some expressions of public opinion differently from others. Certainly all officials find it 'prudent to heed' the opinions of their constituents, but do some constituent preferences get more attention than others? Gilens (2014) analyzes trends in US public opinion and changes in federal government policy over a four-decade period to examine this question. In general, he finds that government responsiveness to public opinion has shifted markedly in favor of the preferences of more affluent citizens, in particular, the wealthiest 10% of Americans. There are some indications that government is more responsive to low and middle income Americans during presidential election seasons and in cases of policy debates in which powerful interests groups are engaged on their behalf. But these are rare exceptions in a growing tendency for government policy to be increasingly driven by the opinions of the nation's most affluent citizens. Gilens claims that "under most circumstances, the preferences of the vast majority of Americans appear to have essentially no impact on which policies the government does or doesn't adopt" (2014: 2).

The Globalization of Opinion Research

Data on public opinion are now collected in almost every country throughout the world. The World Values Survey (WVS) began as the European Values Survey in 1981. Representative samples of citizens were interviewed in 10 western European countries with a common core of questions about moral and social values. For its second wave of interviews, 12 non-European countries were added. The sixth and most recent wave of data collection covers more than 50 countries, enabling researchers to track changes in moral values in a wide range of countries over a period of more than 40 years. One of the most important studies to emerge from the WVS is based on data

analyzed by Inglehart and Baker (2000) showing that traditional cultures have long-lasting impacts on moral values in countries undergoing modernization. This occurs in spite of the fact that modernization "is associated with shifts away from absolute norms and values toward values that are increasingly rational, trusting, tolerant and participatory."

The Global Barometer surveys grew out of the Eurobarometer Survey that was initiated by the European Commission in 1973. The surveys address a wide range of public issues on topics related to European citizenship, international relations, health, culture, and the environment. Similar multinational surveys are conducted for the Latinobarometer, which gathers data from more than 20 000 interviews in 18 countries in Central and South America, the Asiabarometer, which covers 18 countries in Southeast Asia, and the Afrobarometer, which began in 1999 and has completed five waves of data collection in more than 35 African nations.

The Gallup World Poll originated from an international consortium of independent polling companies. The Gallup International Research Institute held annual meetings from 1937 to 1939 at which representatives from 50 different countries shared their findings from polls conducted on a wide range of topics. Today, the Gallup World Poll conducts survey and opinion polls in 160 different countries. The poll is known especially for its comparative measures of personal well-being, which are based in part on a question that asks respondents to describe their life satisfaction by placing themselves on an imaginary ladder with steps numbered 0–10. Results from the poll show that people living in Scandinavian countries are most satisfied with their lives while people in the poorest countries of Eastern Europe, Southeast Asia, and Africa are among the least satisfied. Scholars have used data from the Gallup World Poll to study the relationship between personal well-being, income, aging, and health (Deaton, 2007; Stevenson and Wolfers, 2008).

Abstract

Public policy is a set of decisions by governments and other political actors to influence, change, or frame a problem or issue that has been recognized as in the political realm by policy makers and/or the wider public. Scientific approaches toward public policies have proliferated over the postwar period as the size and scope of government interventions have continuously expanded. The study of public policy includes policy analysis or policy science, which identifies effective policy measures, policy instruments, which a government can employ, and the policy process, which analyses how a government comes to take a decision.

Introduction

Public policy is a set of decisions made by governments and other political actors to influence, change, or frame a problem or issue that has been recognized as being in the political realm by policy makers and/or the wider public. Public policy can also take the form of a nondecision (Dye, 1972) or a deliberate neglect (Klein and Marmor, 2006). Strategic approaches toward public policies have proliferated over the postwar period, as the size and scope of government interventions have continuously expanded. Today, there are still high expectations about the problem-solving capacities of public policies, even though, in the last couple of decades, many policy problems could not be solved. Trust in government is also declining and problem solving has been increasingly taken up by private sector initiatives. These can be found in the form of social enterprises, charities, or business activities.

The study of public policy includes policy analysis or policy science, which identifies effective policy measures, policy instruments, which a government can employ, and the policy process, which analyses how a government comes to make a decision. The fundamental question in the study of public policy is still to reconcile the fundamentally different constraints in the field of politics and the field of policies. While many policies are now available for solving problems and policy knowledge is vastly improved, many policies remain politically contested.

Origins

Until the full democratization of modern societies set in, politics was the process of establishing order and power. Public policies were one part of politics as they were employed to satisfy certain political demands. They were usually part of the political process and not necessarily aimed at particular political goals in their own right or to solve problems. The German chancellor, Otto Bismarck, introduced social insurance to pacify the increasingly restless working class in Germany and to pre-empt sympathy for the fledgling social democrats. The underlying problem of social risks was hardly on policy makers' minds until well into the twentieth century. Democratization, however, gave rise to higher expectations from the public with regard to governmental responsibility. The consequences of the Great Depression led to an increased study of policy tools as a way to stabilize national economies in an international context. The failure to find and implement an appropriate response to the underlying problems of the Great Depression, and the subsequent rise of fascist governments in Europe and Japan, followed by World War II, increased awareness about the need for more clearly designed and planned public policy for both political and economic stability in industrialized countries.

The postwar period, therefore, saw the development of more professional policy planning across the industrialized world and the rise of public policy as a function of governments. In the socialist Eastern bloc all economic and social activities by governments were based on complex planning procedures in state bureaucracies. A detailed command and control structure was applied to major spheres of life. In the Western world, education, health, social, and pension policies became important fields for public policies. But also industrial and economic policy, the labor market and defense were key activities of central governments. Today, public policies have now been developed for almost all issues and questions in modern societies, ranging from birth control and consumer protection to assisted suicide. There is hardly any aspect of modern living which is not touched upon by public policy. Governments have approaches and positions on virtually everything, with maybe the exception of fashion and cultural tastes. But even here major mass media outlets are in the public sector and shape the consumption of popular culture.

The process of expanding public policy to all parts of life was accompanied by a continuous increase of public spending as part of GDP in the industrialized world between WWII and the mid-1980s, as well as a massive expansion of legislative activities and regulation. This has not been reversed by trends toward privatization and deregulation since the 1980s as both generally require new rules and public supervision. Public spending is stagnating at a relatively high level and today's economies cannot survive without active involvement by governments.

The initial enthusiasm for public policy as a problem-solving device has waned. Trust in governments to solve pressing problems is at an all-time low. The first two decades after WWII were full of hope that an orderly approach toward policies could eradicate the most serious problems in modern

societies. Poverty, crime, drug abuse, low skills, and unemployment were seen as social problems which could be addressed and solved with public policies, if enough knowledge and research were applied to find the best solution. These hopes were dashed for several reasons: first, finding good and appropriate policies to address problems was more complex than initially thought. There is still no one decisive answer as to how to eliminate poverty or crime in open societies. Second, potential policy tools such as redistribution, public spending, social spending, and public work schemes are strongly politically contested in all modern democracies, even where they have been proven effective. The policies of the Nordic countries, which generally have higher levels of education and health and lower levels of crime and unemployment, have rarely exported these policies to other areas as they rely on historical political compromise as well as political institutions which were not in place elsewhere. Third, problem definitions were also subject to political contestation: do governments have to be concerned with consumption patterns of their citizens if it affects their health or wellbeing? Fourth, the size of government as well as its role remains a topic of debate. Fifth, policy effectiveness is only one criterion among many for policy makers and often not seen as the most important one. Some policies are not in line with general values or political preferences. Many studies have shown, for instance, that incarceration rarely prevents reoffending. Nevertheless, the value of punishment for offenders remains a strong reason for imprisonment. Finally, policies very often produce winners and losers and impact the political process (Lowi, 1971). Many insights in public health on healthy eating and exercise have not led to policies as they potentially have a negative impact on producers. For instance, the effects of meat and high levels of sugar and alcohol are well known but have not led to effective policies to curtail them. Banning sugar or even increasing information about sugar in food, meets fierce resistance from major manufacturers, and yet tobacco is under heavy attack by policy makers. In other words, the politics of policy making is still the main factor influencing public policies, not their problem-solving capacity.

Policy Analysis, Policy Science and Evidence-Based Policy Making

The academic field of public policy originated in the United States as a turn toward a scientific analysis of policies (rather than politics, as in the much older field of political science). The growth of government and the increasing expectation that governments were to solve specific public problems, such as unemployment, poverty or housing, led to the emergence of policy science as a new approach (Lasswell, 1951). Howard Lasswell suggested that better policy and better government could be achieved through the intelligent use of the social sciences. Just as no energy grid could work without the knowledge of engineers and monetary policy is based on the advice of economists, all parts of government should be organized in a way that independent scientific knowledge would lead the way toward better policy making. For maximizing the effects of policy science, research should focus on three aspects: to be multidisciplinary, problem solving, and normative (Deleon, 2006; Howlett et al., 2009).

In particular the practical application of policy solutions for real-world problems was the driving force for setting up schools and research institutes dealing with public policy. Government bureaucracies themselves integrated policy sciences into their administrative structures during the 1960s. In the United States by the 1980s virtually every federal office had a policy branch (Deleon, 2006). They aimed to identify objective and scientific solutions for clearly defined policy problems. The task of the policy analyst was to apply the best available knowledge from all disciplines to a given problem in order to find the best available solution and to mediate between science and politics. Dunn defined policy analysis, for example, as an applied social science discipline that uses multiple research methods in a context of argumentation, public debate in order to create, critically evaluate and communicate policy-relevant knowledge (Dunn, 1994). Policy science increasingly built on existing knowledge to propose a policy solution. Eugene Bardach, at the Goldman School of Public Policy at the University of California Berkeley, published *A Practical Guide for Policy Analysis: The Eightfold Path to More Effective Problem Solving*. The book identifies in detail the steps toward successful policy analysis as follows: (1) define the problem; (2) assemble some evidence; (3) construct the alternatives; (4) select the criteria; (5) project the outcomes; (6) confront the trade-offs; (7) decide; and (8) tell your story. Steps (1)–(6) would be based on scientific research dealing with a policy problem. Only the last two steps would put the policy issue in a wider political context. The persuasion, argumentation and reasoning were an important part of policy science in addition to policy analysis which determined the best approach.

After an initial phase of enthusiasm for large-scale policy planning, such as the War on Poverty in the United States, or initiatives for economic planning in Europe, the 1970s and 1980s saw an increasing disillusionment with the power of scientifically based policies. Many policy suggestions were not taken up by policy makers and the implementation of policies was found to be harder than the policy designers had anticipated. Also many policy fields are complex and particular measures have a knock-on effect. Attempts to fix one problem create several more (Moran et al., 2006). Primarily in the field of economic policy, the recession during the 1970s triggered by oil-shocks demonstrated the limits of economic management and the fact that governments were not in control of the business cycle. Unemployment, poverty, and low educational attainment returned to the policy agenda. In many countries a new debate about the limits of the state and state responsibility emerged. Whereas previously governments aimed to alleviate social problems, they now seem to increasingly accept the nature of societies as unequal and imperfect.

Today, specialist research institutes and universities deal with specific policy concerns in great detail. Research in economics has advanced the understanding of different parts of the economy and influences public policy a great deal. Sociology, demography, public health, engineering, and environmental studies have also provided many policy suggestions to policy makers. Government bureaucracies issue policy research either by assessing potential outcomes of particular policies or evaluating existing policies. Microeconomic research models incite structures and frequently propose public policies to improve regulation, taxation, and spending.

Policy science today is based on a model of demand (by governments) and supply (by researchers) (Deleon, 2006). Rather than integrating research into government bureaucracies and establishing expanded research and planning units, as was foreseen in the 1960s, many governments rely on a host of university and institute-based research for individual policy problems. Independent research output competes for attention in the political arena and is occasionally used in either parliamentary hearings or government programs to improve policy design. The separation of governments and research institutions also allows for a greater plurality in methods and approaches, as well as political preferences. The hope by Laswell that each policy problem would have one best solution, which could be identified by applying the best knowledge, has been replaced by a market place for solutions that offers different pros and cons as well as different distributional outcomes. Expectations toward social engineering as well as economic management today are much more modest than in the early postwar period. Policy science as a science in itself has been in disarray as it could not establish and institutionalize one dominant approach toward problem solving (Klein and Marmor, 2006). At the same time, the role of scientific advice for policy makers has never been stronger.

Evidence-Based Policy Making

Recently a new form of policy science has emerged under the rubric of evidence-based policy making (Radaelli, 1995). Pioneered in medicine, where evidence of effectiveness is now a major criterion for developing guidance, the British government under Tony Blair engaged in further developing a science-based policy prescription. In the UK, evidence-based policy making was supported by grants from the Economic and Social Research Council (ESRC) to the Evidence Network in 1999. The Evidence Network is a center for evidence-based policy and practice. At the core of evidence-based policy making is the systematic testing of the policy's effectiveness. It includes the counterfactual and asks what would have happened without the policy change. Effects of a policy are measured both directly as well as indirectly. The decision in favor or against a policy is then taken in a cost–benefit perspective which aims to assess the net benefit of a policy change.

Evidence-based policy is used in development policy and has been advanced by the RAPID Outcome Mapping Approach (ROMA) through the British Overseas Development Institute (ODI). It is based on six key assumptions (Young and Mendizabal, 2009). They include first, that policy processes are complex and rarely linear or logical. Simply presenting information to policy makers and expecting them to act upon it is very unlikely to work. They are not purely linear as they have various stages that each take varying lengths of time to complete and may be conducted simultaneously. Strategies must be fluid. Second, many policy processes are only weakly informed by research-based evidence. Third, research-based evidence can contribute to policies that have a dramatic impact on lives. Fourth, policy entrepreneurs need a holistic understanding of the context in which they are working. While there are an infinite number of factors that affect how one does or does not influence policy, it is relatively easy to obtain

Figure 1 The RAPID outcome mapping approach (ROMA). Reproduced from Young, J., Mendizabal, E., 2009. Helping Researchers Become Policy Entrepreneurs: How to Develop Engagement Strategies for Evidence-Based Policy-Making. Overseas Development Institute.

enough information to make informed decisions on how to maximize the impact of research on policy and practice. Fifth, policy entrepreneurs need additional skills to influence policy. They need to be political fixers, able to understand the politics and identify the key players. Finally, policy entrepreneurs need clear intent – they need to really want to do it. Turning a researcher into a policy entrepreneur, or a research institute or department into a policy-focused think tank involves a fundamental reorientation toward policy engagement rather than academic achievement; engaging much more with the policy community; developing a research agenda focusing on policy issues rather than academic interests; acquiring new skills or building multidisciplinary teams; establishing new internal systems and incentives; spending much more on communications; producing a different range of outputs; and working more in partnerships and networks.

As the key lessons from evidence-based policy making show, understanding the relationship between research, policy and implementation is as complex as the older and more traditional policy science. To develop policy advice for policy makers is not easy or straightforward (**Figure 1**).

Tools of Government

Public policies come in many different forms and sizes as governments have a whole array of instruments at their disposal. Policy problems can be defined and solved in many different ways as the following example can illustrate. The pollution of a public space can be stopped by either convincing citizens not to drop their litter; by introducing a fine for littering; by supplying more bins or by giving firms subsidies for removing and recycling the litter. Depending on the approach chosen, very different groups of the public will be made responsible for solving the problem: the citizens through persuasion or coercion; the city council through the provision of bins or private business.

There are many categorizations and typologies of different tools (Dahl and Lindblom, 1953; Lowi, 1971; Salamon, 1981). More recently the discussion of policy instruments is often centered on an individual's behavioral change to solve policy issues. Through 'nudging' individuals are tempted to live healthier lifestyles and thereby reduce health risks which would lead to higher spending on healthcare (Thaler and Sunstein, 2008). Behavioral economics is a relatively new but very active field for policy analysis.

Nevertheless, the most intuitive and still powerful categorization was developed by Christopher Hood (1986). He distinguished between four different types of resources that governments could employ for achieving policy goals: Nodality, Authority, Treasure, and Organization (NATO) (**Table 1**).

Information-based policy instruments often take the form of public information campaigns which address citizens directly. They can either inform them about new government policies, entitlements, approaches or target behavioral change. Governments can also use information campaigns to change the perception of a problem or to influence the mood about a particular topic. This can facilitate or endorse other public policy changes. For instance, commissions and inquiries can be used to put a policy problem on the agenda and raise awareness for policy change. At first glance, information seems to be a weak policy instrument since it cannot enforce a particular behavior. However, many behavioral changes are based on an awareness of a situation. The perception of a particular problem is often an essential precondition for compliance with other policies.

Authority-based policy instruments are regulatory government tools that cover almost all policy fields. Regulation includes rules, norms, standards, directives and legislation. The violation of regulation is frequently punished by law. It is therefore a strong policy instrument in theory as long as the public authority is in a position to monitor compliance. If compliance cannot be observed, regulation is often ineffective. Compliance costs can also be high and outweigh the benefits. Self-regulation or delegated self-regulation can help to improve compliance when those actors who are the recipients of regulation can influence and participate in the setting of the regulation.

Financial instruments generally are very effective if used appropriately. Subsidies, transfers, grants and taxes have a direct effect on citizens' behavior. Taxation on alcohol and tobacco reduces consumption and improves public health. Subsidies to farmers protect them from the effects of falling prices. Grants to service providers establish particular services. Financial instruments are, however, problematic as they can become politically entrenched. Once introduced, it is very hard to abolish transfers, tax-breaks or subsidies as people become dependent on them.

Organization-based instruments are provisions through the government directly or through agencies under governmental control. Schools, tax authorities, prisons hospitals, and armies

Table 1 Policy instruments

are mostly under governmental control. For childcare and other social facilities, voluntary organizations can be supported through government agencies. Market creation through voucher schemes is another way of developing services. While public enterprises have largely been privatized throughout the last two decades, public–private partnerships have become more important. Government reorganization occurs in the context of privatization and the creation of new government agencies for supervising privatized utility providers or transport providers.

Very often governments employ a mixture of all instruments in order to implement public policies. For instance, vocational training in Germany is an important policy instrument that simultaneously keeps the rate of youth unemployment low and improves the skills of school leavers. In order to ensure a high rate of voluntary participation by firms to provide training places, the government runs information campaigns, gives tax breaks for hiring disadvantaged youths, enables and fosters firms' self-regulation with regard to the content of training and runs public training facilities for those who do not find an apprenticeship. These different approaches are not chosen indiscriminately but with the expectation that they will reinforce each other. Often a range of policy tools is employed because the effectiveness of each individual tool is not known.

Which policy instrument will be chosen depends on a number of factors. First and foremost, policy choice depends on the broader institutional context of a country. There are different national approaches toward risk regulation, for instance, in the United States and Europe (Vogel, 2012). There are also differences in legal systems which make the use of regulation more or less appropriate. In some countries public ownership of firms or agencies is more accepted (as in France) than in others (for example in the UK). The use of tax-breaks is heavily used in the United States, where public spending is seen more critically, compared with Europe where both taxes and public spending is higher. Large scale changes often develop as an accumulation of small scale changes and major policy changes occur only very rarely in the context of political upheaval.

Politics and Institutional Constraints

Public policies are often path dependent and policy changes occur incrementally (Pierson, 2000). Once a particular problem is addressed by policies, the chances are high that future policies will be similar. As Aaron Wildavsky pointed out: the main predictor for a federal budget is last year's budget (Pressman and Wildavsky, 1984). Once a particular public policy response to an existing problem has been developed, it is very likely that future responses will be at least influenced if not determined by it. A pension reform in the context of a Bismarckian pension system will not easily give up on pension insurance and move to a Beveridge public pension scheme. Rather, policy makers open up an avenue for another noninsurance pension pillar to lift the burden off the insurance-based pension.

This has several reasons: first, citizens' expectations are shaped by previous policies. Second, policy makers themselves have a cognitive bias toward established responses. Third, political actors might have vested interests based on previous policies and fourthly, the costs for changing an established path continually rise even if the costs of an existing and unsuccessful policy might rise too. Peter Hall (1993) has distinguished between three different kinds of policy learning and has acknowledged the high barriers for fundamental policy change. Third order policy change, which involves a shift of paradigm as to how to interpret and solve a problem, occurs only after much experimentation and several crises, after which existing policies have been proven to have failed.

Besides path dependence and barriers for policy learning there are clear institutional effects on policy making. Not all public policies are equally likely in all institutional settings. Rather, different kind of political systems, political institutions and electoral rules have different effects on policy making. These effects are not well understood yet and research on institutional factors determining policies is still in its infancy (Immergut, 2006).

One influential study that looked at the effects of political institutions on public policies is Lijphart (Lijphart, 1984, 1999). The study distinguishes between consensus and majoritarian democracies. Political institutions in majoritarian democracies provide governments with a strong majority and the capacity to implement far-reaching policy changes which cannot be vetoed by other actors. In contrast, consensus democracies heavily constrain governments in their decision-making power. Variables that are used to classify political systems are the number of political parties, coalition governments, federalism and also the role of the central bank and constitutional courts. Lijphart correlates political systems with policy outcomes such as economic growth, inflation, social spending and citizen satisfaction. He comes to the conclusion that consensus democracies, which are mainly to be found in continental Europe, tend to be the kinder, gentler form of democracy (Lijphart, 1999).

A similar approach is pursued by Iversen and Soskice (2006) who use electoral rules as a major factor determining policy outcomes. They also divide modern democracies into two types: those with proportional representation and those with majoritarian electoral rules. In democracies with majoritarian electoral rules, we tend to find two-party systems. This is because losers of elections are heavily punished and small parties cannot survive. In a two-party system, the middle class voter has the choice to vote for a left-wing party which might tax the middle classes to spend on the poor or to vote for a right-wing party which constrains taxation. On balance, middle class voters will vote for the right, leading to lower levels of social spending in countries with majoritarian institutions. The evidence shows that majoritarian democracies have experienced far more years of conservative rule than of left-wing rule, as well as lower levels of social spending. Similarly but with different arguments, Persson and Tabellini, have argued that in proportional electoral systems politicians maximize votes (and not districts as in majoritarian systems) and tend to go for redistributive policies such as social spending or public pensions (Persson and Tabellini, 2002).

Other studies have looked at the capacity of other actors to constrain governments. Ellen Immergut has, for instance, identified veto points in the policy process, which can be used by opposing actors to stop a particular policy. Depending on

the availability of veto points, some policies, such as comprehensive healthcare, might be prevented by special interest groups (Immergut, 1990). Similarly George Tsebelis has identified veto players in the policy process. He argues that policy change will be more difficult when the number of veto players increases (Tsebelis, 2002).

Theories as to the effects of electoral rules and political institutions have been powerful for explaining redistribution and social spending and, therefore, the size of the government and the welfare state (Huber et al., 1993). They have been less influential for other policy fields and policy change. It is, however, currently undisputed that in advanced democracies there is a major difference between countries with majoritarian and proportional representation for social distribution.

Outlook

Our knowledge about the effectiveness of policies and the role of public policy has vastly improved over the last 50 years. The scientific approach toward policies as well as a more systematic evaluation of existing public policies has created a wealth of knowledge of what works. The move toward evidence-based policy making and behavioral economics will improve our knowledge base even more. In a couple of decades, policy makers in advanced democracies will know exactly what the best approach for solving pressing social and political problems will be.

However, the most effective policies are still not the most likely to be adopted. In public health, a healthier lifestyle through exercise and nutrition is frustrated by producers and consumers of unhealthy products. Introducing taxes or banning sugary drinks have been very controversial and politically contested. The fight against the tobacco industry has been ultimately successful in the developed world while more smokers exist today due to an increase in the developing world. In environmental policy, the predominance of individual transport by car undermines global targets of lower carbon emissions. In global environmental policy, free-riding and collective action problems undermine common solutions. In education policy early childhood education still receives the least funding even though experts agree that early investment for children is highly effective. There are many more examples that prove that policy makers do not choose the best policy to address public concerns. Rather, political interests, power constellations and political institutions heavily influence the choice of public policies. The flaws in the democratic policy process which gives other interests, including a general skepticism toward government intervention in society and markets, an avenue for lobbying and intervention, has so far prevented a more systematic science-based policy approach.

Recently, public policies have also been increasingly influenced by private actors. Business and civil society actors are far more active in policy debates than they were before. Iron triangles of policy makers, where bureaucrats and experts jointly dominate a policy field have been replaced by a more fluid policy process. Governments control policies less now than they did in the past. They also use many more market-based policy instruments than before. This is not necessarily based on evidence but more often on general political motivation to include the private sector in the provision of services. Privatization and deregulation have created private interests in previously government controlled policy fields. These have created problems of their own which are still ongoing.

On the whole, the field of public policy is likely to further expand and professionalize. Modern societies are facing many problems which governments are expected to solve. Finance and trade, climate change, global migration, and health threats have evolved into global policy fields as crises can be contagious and are not confined to national borders. The application of existing knowledge to policy problems will remain a major issue for the years to come even though the exact form of policy research and application is likely to change.

Abstract

Since the 1970s graduate education in public policy has come to dominate elite graduate education for public service in the United States. It has done so through an emphasis on the imparting of a variety of rigorous analytic techniques – centered on microeconomics, descriptive and inferential statistics, and political and organizational analysis. Today, however, public policy education and the field of policy analysis faces a number of challenges – a decline in the belief that social problems can be solved through governmental action, the continuing weakness of the political and management parts of the policy curriculum, the potential negative effects of trying to serve an ever more heterogeneous set of student interests and expectations, and the failure of the field to foster the equivalent theoretical breakthroughs that finance theory provided for professional business administration programs.

What Is Policy Analysis?

Before describing public policy schools, it is first necessary to describe the field of policy analysis. Although neither academics nor practitioners of policy analysis have been able to agree on a common formal definition, almost all would agree that policy analysis involves the use of formal reasoning to formulate advice for the solution of problems faced by governmental and nonprofit sectors. Of course, political leaders, decision-makers, managers, and administrators have relied on advisors over recorded time. Scholars and practitioners in many fields, particularly in the professions such as law, medicine, public health, social welfare, and urban planning, claim to incorporate policy analysis as part of their task. How do public policy schools and their graduates differentiate themselves from the mass of advisors then? They do so by using formal analytic techniques to make informed guesses about the outcomes of alternative choices, as they would be implemented on the ground in the real world.

The modern policy analysis movement had its genesis in the United States and has spread very slowly, if at all, to other countries. For that reason, the history of public policy as it evolved into an academic curriculum is a history of the application of policy analysis in the United States.

The staffing effort of the World War II and the subsequent Cold War with the Soviet Union brought the policy analysis movement into existence. Although many historians of the policy analysis movement point to Daniel Lerner and Harold Lasswell's call for a policy sciences field that would apply reasoned advice to all stages of the policy process (deLeon and Steelman, 1999; Lerner and Lasswell, 1951), in practice the field developed with the application of what might be called the optimization sciences – particularly micro-economic analysis and the techniques of operations research – to policy choices. These techniques were first used in this way during the World War II when the need for war mobilization led to a planned economy significantly replacing the market economy. After the war the new techniques found a home at a newly formed home for defense analysis (the RAND Corporation). Ultimately these techniques, and many defense analysts, found a home in offices or ministers of defense and then diffused throughout government. The analytic offices that were set up became an established source of policy advice using the techniques of benefit-cost analysis, cost-effectiveness analysis, operations research, and policy evaluation. These techniques became the heart of the new policy analysis curriculum.

Since the 1970s in the United States, public policy schools have become major centers for graduate education for service in the public and nonprofit sectors in the United States. At many prestigious US universities they have replaced schools and programs of public administration. Their number has grown from under 10 in 1970 to over 60 in 2000. Many existing public administration programs, moreover, have incorporated parts of the public policy curricula, and in some cases have adopted public policy concentrations.

The growth in public policy schools and programs has been associated with the creation of an academic field complete with an association – the Association for Public Policy Analysis and Management – and a journal – *Journal of Policy Analysis and Management*. Of equal, if not greater, importance has been the spread of the intellectual approach of policy analysis as graduates of policy schools have replaced traditional public administrators in high-level staff positions at the US federal, state, and local governments.

As graduates of policy programs have replaced students of accounting and public administration in various governmental staff agencies – particularly budget offices – the policy analysis movement and approach have been institutionalized within the governmental service. This institutionalization was reinforced by the slow economic growth and resulting budgetary constraints of the 1970s and 1980s which forced decision-makers to continually face tighter constraints and trade-offs. New institutions, such as the Congressional Budget Office of the US Congress, were largely staffed by those with policy analysis training obtained either in schools of public policy or PhD programs in economics.

These new staff organizations reflected the norms and values of their dominant staff professions – the graduates of

economics departments and policy analysis schools and programs. Chief among these was a belief that, all things being equal, markets are the best way to allocate society's goods and services. That a decision to use other allocation mechanisms was justified only on grounds of equity or rights (the distribution of benefits and costs and/or the existence of some activities that society believed should not be freely exchanged), or when one could show that markets had failed and that governmental intervention would (not could) lead to a more economically efficient allocation than was the case under the failed market. This reliance on markets separated the new policy analysis movement from the traditional planning approach and built within the policy analysis framework a conservative bias when it came to justification of public sector activity.

The centrality of the norms of economics to the new policy analysis movement led to a belief that analysis of policy requires the laying out of the trade-offs inevitable in the creation and implementation of policy. These trade-offs are reflected in the centrality of two ideas of economics – opportunity costs and the margin. The policy analyst relies on opportunity cost to inform the decision-maker that no option is free, that one can always use the resources for other activities. The concept of the margin allows the economist or policy analyst to tell the decision-maker what he/she can obtain from adding or subtracting one unit of resources. The use of these concepts separates the economist and policy analyst from the political analyst, who often seeks to suppress trade-offs so as to increase the membership of political coalitions.

A third effect was a conscious attempt to present decision-makers with analyses of policy options that make choices concrete by clearly defining problems, setting out possible solutions, and specifying the criteria to be used to judge those solutions so that those decision-makers can evaluate the solutions in a comparative, predictable manner. Although students of policy analysis often wrote about qualitative as well as quantitative indicators, in practice practitioners of the new field found that their comparative advantage vs other advisors was in the use and presentation of quantitative measures – particularly those in a benefit/cost format.

The reliance on analytic techniques and on policy options separated economists and policy analysts from traditional American public administrators. Since the progressive era and the early academic writings of Woodrow Wilson on public administration (Wilson, 1887), students of public administration had operated under the belief that it was possible to separate the creation of policy from its efficient administration. Although by the 1960s most public administrators knew that this dichotomy between politics and policy on the one hand and administration on the other was a myth, much, if not most, of the public administration approach still centered on the efficient running of bureaus and departments. Consequently, to a great extent, the educational core of masters in public administration programs reflected this approach with required courses on the functional skills needed by a line manager – budgeting, organizational behavior, personnel management, and the role of an unelected civil servant in representative government.

What Are Public Policy Schools and How Do They Differ from Other Programs?

The first public policy schools and programs were created in the US in the late 1960s. With considerable philanthropic support, 1971 had founded nine schools or programs in the United States. In a pattern that has continued to this day, several existing programs quickly adopted the new approach and curricula of the policy school movement.

The advocates and sponsors of these new schools and programs sought to apply the new optimizing techniques of policy analysis to the problems facing nations in the late 1960s – particularly the problems facing urban areas. At this time it was still widely believed that government could solve social problems if the right policies were found, created, adopted, and implemented. Thus, the initial educational effort sought to support positive public sector activity to solve problems, a view that has much less support today. The creators of the new programs also sought to do for education toward public service what the changes in business administration education had done for business administration in the mid-1950s – replace a curriculum centered on institutional description and anecdotes with one grounded on analytics.

Similarities Across the Schools

Although one can point to many differences among the original nine policy schools and programs – one had a heavy emphasis on undergraduate education, a second only offered a PhD – viewed from afar their similarities far outweighed their differences. With the exception of the one that only offered a PhD, all focused their graduate education efforts on a Masters degree that was viewed as a terminal professional degree rather than a step toward a doctorate. In most cases they labeled this primary degree the masters in public policy (MPP).

Concentration on Analytics and Professionalism

The basic analytic public policy core set of courses has remained quite similar since the founding of the nine original schools. It centers on a combination of three yearlong sequences of analytic skill offerings – in economics, quantitative methods, and political and organizational analysis – one or more workshops in which students undertake policy analyses for real, as against hypothetical, clients, and a required summer internship. Some programs also required courses in individual and/or policy ethics. Others required courses in legal analysis. Initially the economics sequence centered on microeconomics, although several of the programs required a microeconomics–macroeconomics sequence. Although centered on courses on descriptive and inferential statistics, many of the initial required curricula also included material drawn from decision analysis, game theory, and operations research.

The political and organizational analysis sequences were included so that students trained in technical skills would also graduate from the programs with the political and managerial skills needed to enact, implement, and administer policies. Of all the required sequences in the policy analysis curriculum, political and organizational analysis has remained the most

problematical. From their inception public policy programs rejected the public administration separation of politics from administration. Instead it was assumed that to be an effective analyst one had to be an effective political actor and manager. But unlike economics with its instrumental approach, the academic discipline of political science was largely descriptive and as such was less useful for a professional curriculum. This posed and still poses a great challenge to the public policy faculty charged with the political and managerial core of the policy curriculum. Attempts have been made at a number of institutions to take the findings of political science and public administration research and, through the use of decision forcing case studies, to build a prescriptive and strategic approach to management. Students were challenged to go from answering the descriptive question, "What are the political forces or organizational tendencies which affect the kind of policy we can formulate?" to the more instrumental question, "What do I, as analyst or manager, need to do, as I shape my policy prescriptions or implement the chosen policy, to ensure that the political forces and organizational tendencies do not succeed in frustrating or changing desirable policy in undesirable ways?" (Fleishman, 1990: pp. 743–744).

Many observers have felt that this attempt has been only partially successful, however. To overcome this deficiency some scholars have focused on identifying examples of 'best practice' that might form the basis of improved political and organizational behavior (Bardach, 1994, 2000). Others, criticizing the lack of scientific rigor in this approach, have urged their colleagues to create a body of knowledge in which statements of appropriate political and organizational actions are subject to formal hypothesis testing (Lynn, 1994).

The professional nature of public policy programs is reflected in the fact that, unlike the traditional pattern in which professional masters students simply take graduate courses offered by the economics and political science departments, the required policy analysis courses were and are especially designed for a professional program. The goal in most cases is to recast traditional material in a policy centered, problem solving framework and to present the material in an instrumental rather than descriptive manner. As indicated, political science approaches are largely descriptive, and the new programs, therefore, had to take this material and turn it on its head by presenting it in a fashion that would allow future practitioners to use it as a lever to achieve policy and managerial goals – what might be called political and managerial engineering.

One constant across nearly all the original courses was the focus on domestic policy. Over time international material slowly entered the curricula, but this occurred largely through applications of the analytic skills of the curricula (such as benefit/cost analysis) to international situations, such as whether a water project should be built in another country. In recent years several policy schools have moved into the area of economic development, but almost all have avoided the traditional subjects of international relations and country analysis.

Differences between Public Policy and Public Administration Programs

The new public policy programs sought to replace the existing public administration educational model of public administration. In addition to their focus on analytic skills, the new programs differed from their public administration counterparts in their large required set of core courses, the absence of required concentrations, and the greater number of economists and statisticians on the faculty.

Existing public administration programs had a small set of core required programs (four to five courses) and lasted a year to a year and a half. The new public policy programs were two-year programs with a large number of required core courses (at least a full year's worth at a minimum and in some cases up to two-thirds of a standard two-year course load). In most cases students were required to take these courses in a set sequence. The average public administration program (MPA) offered many specialties or concentrations (with a mean of five in 1984) (Ellwood, 1984). Initially at least, MPP programs almost totally focused on the analytic techniques taught in their large cores. In 1971, in the United States, the average MPA program faculty member's doctorate was either in political science or public administration (21 and 20% in 1971). Economists represented only 9%. In the new public policy schools and programs economists represented a plurality (31% in 1971) and in some cases a majority of the faculty with political scientists being the second most represented discipline (23%) (Ellwood, 1984).

Changes and Challenges to Public Policy Schools

Masters programs in public policy currently dominate graduate education for public and nonprofit service in the United States. Graduates from the programs are now found in key decision-making positions throughout government and the nonprofit sector. However, recent developments provide a challenge to the future of the approach and the field.

The Decline in the Belief That the Public Sector Can Solve Problems

The public policy school initiative was fostered by the belief that better public policies could lead to the solution of public problems – particularly those of the poor and of urban areas. Over the past three decades this belief has attenuated if not disappeared in the United States and elsewhere. To paraphrase Ronald Reagan, in the United States government is now seen as the problem, not the solution. Public service itself has become less attractive. The private sector increasingly has come to be seen as the creator and locus of heroes. Private sector remuneration has grown at a far faster pace than public or nonprofit sector pay.

The effect of all these changes has been to draw graduates of public policy programs away from careers in the public and nonprofit sectors toward jobs in the private sector. One recent study found that between 1973 and 1993, in the United States, the percentage of MPP graduates taking jobs in the public sector declined from 76 to 49% (Light, 1999). At the largest US MPP program this percentage dropped to 28% for 1 year in the late 1990s before rebounding to the mid-40% range. This trend poses this question, will policy programs continue to attract the 'best and the brightest' as they have over the past three decades?

The Difficulty of Management and Leadership Education

As indicated above, from the beginning of the policy school movement it was understood that high technical skill was but a necessary condition for an effective policy analyst. The sufficient condition was the acquisition of political, leadership, and managerial skills. The inclusion of a required sequence of political analysis and management in most programs was meant to impart these skills. But this effort has always been the most problematic endeavor of public policy education. Academics simply know less and have a more difficult time imparting what they know to practitioners in these areas than they do when it comes to technical skills. Moreover, from the beginning, management skills were grafted on to a curriculum focusing on the skills needed by staff analysts. In contrast to masters of business administration programs in business schools, where the entire curriculum (or at least the first year of required courses) was seen as management education, policy schools sought to condense courses in accounting, finance, marketing, and operations into one or two required offerings. The result has never been totally satisfying.

The Trade-Off between Breadth and Depth

The original public policy curricula focused on imparting the skills that would be needed by policy analysts who, acting as advisors to decision-makers, would create policies that would hopefully solve society's problems. Over time policy schools have moved away from this narrow focus on the training of staff to a broader focus of training future managers and leaders. Moreover, the initial narrow focus on domestic policy has also broadened. Today the policy schools seek to serve the needs of students with a wide set of career goals. Some want to become elective officials, some political activists, some social activists, some career civil servants, some managers of nonprofit organizations, and some private sector consultants. The percentage seeking careers in technical policy staff positions has become smaller and smaller. As the programs have tried to meet the needs of this increasingly diverse set of students, they have to some extent lost the coherence and depth of the required set of skills that made up the core of their curricula.

As they have tried to serve future elected officials, political activists, public and nonprofit managers, as well as policy analysts, some policy schools have dropped such topics as decision analysis and operations research from their core set of requirements. Others have moved to the creation of tracks or concentrations, with some providing more quantitative, analytic rigor. Some have approved these changes as responding to the needs of a new set of students while others fear that public policy by trying to be relevant to all will lose its distinctive purpose.

The Intellectual Challenge

Professional education always faces the challenge that it is simply an applied or less rigorous version of the material offered by the traditional academic professions. Frequently this charge is misplaced. The need to apply theory to actual situations often leads to new breakthroughs – sometimes theoretical breakthroughs. Such was the case with the creation of the modern theory of finance in business schools.

It was hoped that implementation theory or principal-agent theory would be the public policy equivalents of the business schools' finance theory. But this has not occurred. Implementation theory has never got beyond its inductive beginnings and principle-agent theory is limited when applied to the multiple-goal, multiple-agent world of the public sector (Moe, 1984). This has meant that public policy education has remained derivative and applied. For the long-term health of the public policy movement within the academy, overcoming this weakness is perhaps the greatest challenge to the field.

Public Policy: Ethics

Abstract

There are many ethical dimensions of public policy. Public policy as actions to solve the collective problems includes directly or indirectly making ethical judgments. Public policy takes into account reconciliation of conflicting interests of individuals, groups, and organizations which is based on the values agreeing which influences on the objectives, principles, and styles of policy implementation. Ethical judgments about selecting more and less important as well as more positive problem solutions are present on all stages of policy cycle.

Public policy refers to structuring the government and society actions, which is based on objectified knowledge and is taken to solve the key collective problems. These activities are carried out by using tools such as regulations, public programs, and strategies, stimulating cooperation, arguing, debating, studying, developing positive incentives to adopt expected attitudes, indicators of action effectiveness, evaluation, expertise, as well as by institutions including public offices and networks of commercial and nongovernmental organizations (Howlett and Ramesh, 2003). Analysis of public policy includes both actions that are implemented, those that are not implemented, and those that represent alternative solutions to problems and may be taken.

Analyze and implementation of public policies is a cycle which usually includes the successive steps of agenda setting, policy formulation, decision making, policy implementation, and policy evaluation. There are different styles of action at different stages of policy cycle, which are subject of ethical choices and decisions of individuals, groups, and organizations (policy entities, actors). Public policy can also be understood as functional and technical aspect of governance, whose essence is the control over public resources that need to be redistributed. The choice of mechanisms and logic of redistribution requires an ethical judgment. There are many types of public policies. Among the main are sectoral policies – covering one thematic issue (e.g., health policy, education policy, environmental policy, innovation policy, economic policy); horizontal – crossing various topics (e.g., regional policy, family policy, social cohesion policy); and strategic, redistributive – related to financial transfers from one social group to another.

Ethical Decision Making and Public Policy

Ethics concerns the assessment of activities that we intent to take or do not intend to take. Includes consciously or subconsciously assessment in terms of good and evil, positive and negative actions, justice and injustice, as well as explaining how people define these differences. Choice of public policy is related directly to such ethical judgments during selecting what matters most and what matter not at all in area affected by that policy. Ethics can be understood as a theory of morality or customs and habits. Morality as a social phenomenon is intended to regulate relationship between individuals and social groups. Morality involves views and beliefs actually functioning in society, manifested in people's attitudes toward others, relations between them, and the capacity to cooperate. Morality is a form of social control including evaluation, feedback, norms, sanctions, penalties, awards, role models, and ideals. Ethics is therefore a set of norms and ethical judgments which characterize a society or a certain ethical system (e.g., professional ethics, social ethics, honorary ethics). Ethics is divided into descriptive ethics – descriptive explanations of the morality; normative ethics – evaluative analysis and assessment of morality; applied ethics – applying norms or standards to actual situations, issues; and meta-ethics – philosophical analysis of moral standards and assessments. Ethics includes the theory of values, that is setting ontological status of values, their hierarchy, and their possibility to achievement by human. Based on research ethics as a science formulates sets of rules enabling the implementation of the selected values. Values are all valuable, worthy of desire and choice of things, purposes, and meanings of human actions.

Applied ethics is mostly related to public policy as a moral reasoning and behavior of policy makers, policy analyst, and other stakeholders. Ethical judgments are expressed here by people behavioral choices with social consequences, allocating resources, entitlements, and authorities. In Western tradition, ethics was always related to politics (Capurro, 2005; Wolff, 2011). Basic relationships between public policy and morality can be described as four approaches (Dębowski and Jedynak, 1999). These are the primacy of politics over morality, the primacy of morality over politics, recognition policy and morality as two autonomous areas, as well as the unity of politics and morality. The first approach assumes that political interest is more valuable than the existing moral principles and if whenever breaking the rules and norms is needed this can be done – because 'the end justifies the means.' This position represents, among others, Machiavellian doctrine. Second approach – the primacy of morality over politics – assumes that loyalty to moral integrity is the most important and states that this position shall legitimate any political action. Among representatives of this position were Socrates and Mahatma Gandhi. The third approach is based on the assumption that politics and morality are two autonomous areas. This view assumes that political actions are taken by individuals and groups as far as they moral standards allow

to it. At the same time separation of morality and politics is assumed here as equivalent to no engagement into politics of those persons who are not politicians. This view was formulated by Julien Benda. The fourth position is assuming unity of politics and morality. It is considered here that all policies are evaluated with regard to their moral significance. At the same time the abstract moral standards should be subject to political assessments of effectiveness.

The three most important contemporary theories of ethical decision making in public policy are consequentialism, deontological ethics, and virtue ethics (Sullivan and Segers, 2007; Boston et al., 2010). Consequentialism is related to evaluating human actions by good results, best outcome, the greatest possible increase of pleasure over pain, and the possible satisfaction of preferences in welfare economics. Critics show that this approach countenances sacrificing the interests of a few for the sake of the many, that there is no possibility to estimate all the possible or even probable consequences of a particular action or policy, and that the calculation of consequences is always subjective selection and interpretation of beneficiaries. Deontological ethics points out moral obligations or duties that people should fulfill apart from consideration of consequences. Rights and norms are priority. People should be treated as ends rather than as means to purposes outside of themselves. Deontological approach promotes using published codes of ethics, constructed by professional associations and public agencies. Virtue ethics refers to the sources of people morality in their inner life and character. This approach is focused on certain ideals toward which people should strive to development of their humanity such as honesty, courage, compassion, generosity, fidelity, integrity, fairness, and prudence.

In practice none of these approaches independently provides a complete guide to action under all circumstances and on all stages of policy cycle. Policy makers and analyst may employ different ethical principles and change them to improve policy outcomes.

Ethical Concepts in Public Policy

Number of ethical concepts are used in public policy studies and practice. Particularly important are the concepts of interest, values, principles, and policy intervention styles.

Interest

The ability to create public policies adequate to solve the problems in the country can be understood as the ability to preserve its attributes of sovereignty. In other words, well-prepared mechanisms of public policies give a chance to adapt the country and its society to functioning in modern conditions, that is to compete for resources that will allow a decent quality of life. In this sense, public policy is a set of skills on management available public resources to achieve the highest possible added value for society (Zybała, 2012).

Ethical decision making is a highly complex process in contemporary public life. The difficulty lies here in the fact that public policy is usually practiced in a situation of limited resources. Therefore it requires from government the ethical decisions on selecting activities that should engage these resources for best results (Bellinger, 2007). In addition, public policies are implemented in a situation where different social groups have different or conflicting interests. These groups have different resources, strength, and ability to pursue their interests. Implementation of policies in an efficient manner usually requires the establishment of a consensus among them or even a framework of consensus, which is, for example, public interest, social interest, or national interest. Excessive social conflict may in fact result that the economically weakest groups will hamper (by, e.g., protests, strikes, and social campaigns) important public actions and reforms. Therefore, governments typically run processes such as social dialogue and consultations in various forms.

Interests, as benefits of individuals, groups, or organizations usually includes the values and based on them rules of conduct (Supińska, 2008a). Interests primarily are features that enable and increase the chance of their satisfaction, they tend to give free access to the means of satisfying them, and they cause actual high level of satisfaction. Diagnosis of interests requires a comparison of benefits and losses that may bring a concerned action in a specific situation. Thus, the interests are actions based on reflexivity, in contrast to actions based on impulses, emotions, or feelings. Conflicts of interest arise from the adoption by different individuals, groups, and organizations of different values, principles, needs, and goals, that although may be beneficial for some, can also be bad and harmful to others (Shue, 2006). For example, the decision to build the highway can improve transport of goods, but also degrade the quality of life of communities living close to it, increase the number of fatal traffic accidents, and lead to the destruction of valuable natural habitats; funding of research on human genetic material may raise questions about using their results for medical and military aims; policy on illegal migrants can protect the jobs of citizens in current country, but it can be implemented by rigorous methods that leads to violations of human rights and damage the country's positive image abroad.

Stakeholder analysis in public policy is useful for mapping of the power and interests of different groups (stakeholders) and resulting in a diagram that helps to plan their participation in policy implementation. This includes then, for example, informing and empowering stakeholders (Hermans and Cunningham, 2013). Diagnosis of interests and actors may also serve as a basis or justification for a program of action that will achieve that interest. For example, the program of education development at the same time may aim to increase the intergenerational relations and to protection of nature after analyzing the expectations and opportunities for the involvement of older and younger people. Democratic procedures in the political system allows the articulation of interests. To gain political supporters' interests can be expressed in terms of protecting the interests of vulnerable groups. For example, the interests of our company is the interest of the country and the interests of many small shareholders, who work hard and save money; assistance to the poor is not to summarily grant money (short-term and material interest), but on arousing and sustaining motivation to work (long-term and intangible interest). Public policy therefore requires ethical actions in the interests of the

powerful and the weak, dispersed, and concentrated interests, public and particularistic interests.

Values of Public Policy

Values are what the individual, group, or organization considers as desirable, worth achievement, and action. In public policies primarily evaluated are social relations, the state of meeting the needs, institutions, and relationship between man and nature. The values of social relations includes, for example, justice, freedom, solidarity, equality, and cooperation. The values associated with the meeting the needs are, for example, social security, welfare, health, dignity, and self-realization. The values appearing in evaluation of institutions include self-governance, agency, partnership, common good, and efficiency. The relationship between man and nature determines among other values such as work and ecological balance. Indicators of choices are individual and group behaviors including verbal (e.g., demands, evaluation) and nonverbal (e.g., efforts to gain access to desired goods, emotional states, such as satisfaction or dissatisfaction).

For the public policy crucial are relationships between the values of individuals and groups (Supińska, 2008a). These values can be fully compatible with each other (internalization of the group characteristics by the individuals). They can also be partially compliant when individual accepts some part of the group values and recognizing them as a tool for achieving individual values. For example, some individuals accept freedom in social life since this can guarantee their own freedom. The third type of relationship is inconsistency of group and individual values. This occurs, for example, when individual matured in different sociocultural context and not adapted to the new environment or when is rebelling against the group values. Moreover public policy is examined whether the values adopted by the individuals are in accordance with the values advocated by various entities that are creating and implementing public policy. Thus analyzed whether the values underlying the selected public programs are known for members of the society and whether they agree with the values of individuals and groups. Values in public policy are used for programming, organizing objectives, motivate to action, and justification of adopted legal norms. Knowledge of the society values give possibility to anticipate the arrival of new needs, increasing or decreasing of already occurring needs, or the efforts to meet the needs in a new way, by other means.

Valuing by public policy actors involves the use of assessment criteria related to the broader social, economic, cultural, political, and environmental context. For example, those are criteria on obligatory features (responding to the questions: what is consistent with the values? what corresponds to the norms and standards? what is good for society and for the development of the human person?) or instrumental features (whether achievement of group values will lead to the individual values? whether the implementation of the individual values is not detrimental to the common good?).

There are many sources of values in public policy. These include, among others, ideologies, social and economic doctrines, customs, and attitudes of significant moral and scientific authorities. In modern societies particular importance to ethical debates in public policy is gained by public opinion and mass media (radio, television, Internet), which need guarantee of speech and freedom of the press (Capurro, 2005). Choices of values in public policy and therefore choices of aims, principles, and their implementation programs take place under conditions of conflict of interest and building compromises. Public policies are not, therefore, implementing a rather uniform and consistent value systems.

Values also defines the objectives and principles of public policy. Public policy objectives are determined by groups and organizations during policy formulation. These objectives may be general such as comprehensive development, economic stability and competitiveness, social cohesion, high quality of life, access to nuclear power, adaptation to climate change, and ensuring help for refugees. Under such general goals are specific objectives such as within social cohesion: improving the position of vulnerable economically and socially groups, inequality and poverty alleviation, minimizing the social risk. Fundamentally ethical questions may concern whether these and other goals are actually important and if so how and why exactly they should be achieved (Supińska, 2008a).

Principles of Public Policy

From values are derived the principles of public policy, which can be understood as general guidelines and standards of activities, which should be guided by public policy actors in achieving their goals (Supińska, 2008a). These rules are different depending on the value systems defined in various social and economic doctrines as well as depending on the values adopted and implemented as significant (not always consciously) by public policy actors (which is described as policy style). The principles are an expression of values and directives designed to protect them.

Certain public policy principles are the same as values. For example solidarity as a value describes the desirable attributes of social relations and institutions, and at the same time is the principle used as part of the public policy instruments such as social security systems. For example, self-governance is both a desirable feature of the institutions and the principle of their organization in form of the territorial public administration.

Among the principles of public policy can be distinguished: comprehensiveness, self-limitation, common good, providence, forethought, self-help, solidarity, subsidiarity, participation, sustainable development, self-governance, and multisectorality (Luks, 2005; Bryner, 2006; Supińska, 2008a). These principles can be described as follows:

- The principle of comprehensiveness means that public policy entities should consider all the interests and opportunities to achieve goals and analyze all internal and external factors that may affect their usage.
- The principle of self-limitation means that the government does not have to intervene in all possible areas and sectors of the economy and society, but should choose areas for action.
- The principle of the common good (cohesion) is the realization of individual interests so as to minimize conflicts between them (e.g., environmental conflicts, conflicts between the individual and social interests).

- The principle of providence means that under conditions of limited resources is essential to reduce costs but also to limit intervention, which when is used in excess can inhibit the private and social initiative.
- The forethought principle means that the safety of the individual can not only be the result of benefits from the public, but should also result from individual responsibility for its own future. Forethought is the ability to give up part of the ongoing benefits to meet future needs, and the pursuit of such activities, which minimizes the risk of threats (e.g., saving, healthy lifestyle, organization of insurance).
- The principle of self-help refers to the existence and development of mutual aid of people struggling with similar problems in life as well as support by stronger people for the weak. This assistance usually takes place within a small, informal groups.
- The principle of solidarity is most often understood as a transfer of social risk consequences from individuals to society as well as the superiority of the common interests of society members over the interests of individuals, groups, and social classes.
- The principle of subsidiarity means the adoption of a specific order in which the various institutions undertake interventions such as providing support to the poor. This principle is based on the support in the first instance derived from closest entities (e.g., family, local community), and later help from the state institutions.
- The principle of participation describes an organization of social life, which allows individuals to the full realization of their social roles, and allows groups having equal position in society. This rule specifies the possibility of being a member of different social groups and communities and participate in their actions.
- The principle of sustainable development refers to the integration of political, economic, and social action on preserving the natural balance to ensure the possibility of satisfying the basic needs of both the present and future generations.
- The principle of self-governance is the implementation of such values as freedom and human agency. It is achieved through the organization of social life which guarantees individuals and groups active participation in existing institutions and creating new institutions (informal entities and no-governmental organizations) to better meet the needs and pursue interests.
- The principle of multisectorality refers to simultaneous functioning of different entities of public policy. This include public entities (public administration), commercial entities (private, market), and nongovernmental organizations (civil society, voluntary) that provide resources and services aimed at meeting the needs of society.

These principles do not cover all which are present in the public policy making and implementation. Different types of public policies such as economic and social policies are characterized by different rules. For example, social policies in liberal regimes of welfare state are less focused on solidarity than on forethought and individual savings. While conservative regimes are highlighting subsidiarity and solidarity.

Policy Style

Styles of intervention are derived from public policy values. Policy style concept refers to the assumption that human behavior is important factor in ethical choices and decisions of the policy actors which influence on selecting and using more or less persuasive instruments to achieve policy objectives (Supińska, 2008b). Behaviors are to a large extent rational decisions of people based on the use of their freedom and to pursuit of their life aspirations. However, the behavior of individual groups, for example, employees, students, parents, consumers, criminals, sick, teachers, police officers, and doctors, may differ from the socially expected norms. For example, teachers may focus on work with good students and not promote equality of opportunity for all, consumers can choose cheaper but less healthy food, police officers may be willing to accept bribes. Public policy interventions primarily aim to prevent further dissemination of the behaviors with negative social consequences as well as intervene to maintain and strengthen the already existing positive behaviors, and seek ways to mobilize people to achieve objectives recognized publicly as the correct.

Policy style (style of policy implementation) refers to a set of public policy tools that are adapted to the characteristics of program recipients, which are the causes of undesired behaviors. The choice of intervention style should be preceded by research and public debate which will allow to understand the reasons of undesirable behaviors, overcoming stereotypes, to recognize the social, economic, administrative, political, and environmental conditions of that behaviors as well as to choose relevant objectives and principles for implementation of public policy.

Four basic policy styles may be described (Supińska, 2008b). These are liberal style, caring style, stimulating style, and rigorous style. Liberal style proves to be effective if the only problem with the policy recipients, who have appropriate aspirations and competency, is that they cannot realize their ambitions due to barriers that appeared in their life (such as low education, living in periphery region, lack of institutional capacity). Activities in this style gives freedom to individuals and groups, expressing confidence to their competence. Caring style can be implemented when the main reason for lack of desired behavior is the lack of skills and abilities among policy recipients. Recipients of programs based on this style are treated as persons that need permanent or transitional support until they achieve the desired behavior, skills, and competencies (e.g., help for people with disabilities). Stimulating style assumes that individuals, groups, and organizations can and may keep from negative behaviors or take the socially desired behaviors, but they do not want to (e.g., people choosing to drive they own car than public transport). This style assumes that the desired behaviors can be achieved by offering people some valuable benefits in return. For example, unwillingness to change the organization of business in accordance to the principles of safety and low energy usage can be reduced by proposing a public financial contribution to these investments; the reluctance to change the location of plants can be reduced by lowering taxes. Rigorous style refers to using sets of policy tools that may force the desired behavior. It is assumed here that recipients of the program (e.g., alcohol abusers or

criminals) are able and may but do not want to abstain from condemned behaviors. So that the desired behaviors can be activated upon them only under the pressure of fear from the onerous sanctions (e.g., they do not want to live honestly, but even more do not want to go to jail or pay the penalty).

Policy styles are also varied in different countries due to the various relationships between government and the public (consensus or imposition) as well as due to dominant approach to problem solving (anticipatory or reactive) (Richardson et al., 1982). During formulation of any public programs is reasonable to determine the style which will be fundamental in pursuing of specific objectives. It should also be noted that, in practice, public policies are combinations of the various styles. The different stages of public policy may cover different possible styles. For example on the agenda-setting stage there may be used styles of outside initiation, inside initiation, consolidation, or mobilization (Howlett and Ramesh, 2003). While on the stage of policy implementation may be chosen institutionalized voluntarism, directed subsidization, representative legalism, or directed provision.

There are also different sequences of using policy styles. For example, first may be assumed the citizens' freedom, then the punishment of those who abuse this freedom, then may take place reducing undesirable behaviors of the punished or encouraging to change aspirations. Each style allows not only to achieve short-term objectives of the program but also to contribute to the long-term transformation of personality and attitudes of citizens. This effect is particularly evident in the societies in which there has been long tradition of using rigorous and caring styles by state that also includes interventions into private life (e.g., it affected on low rates of social trust and citizen activities in postsocialist countries like Poland and Hungary).

Ethics in the Policy Cycle

Ethical decision making occurs at all stages of policy cycle (Howlett and Ramesh, 2003; Donahue, 2008). Each stage includes different disputes over values and ethical dilemmas:

1. Agenda setting is a process by which problems come to the attention of governments. This stage includes problem recognition by public, private, and nongovernmental organizations. Important issues are selected by governments into agenda as those that can and should be resolved. Ethical decisions are made during selecting issues because alternative values of policy makers may lead to different choices and objectives. Ethical judgments are also made during considering resource that may be used and stakeholders that interests should be satisfied.
2. Policy formulation refers to how policy options are formulated within government. It starts from policy analysis by which possible solutions to problem are identified and proposed. Crucial part is cost and benefits analysis of material and nonmaterial resources. Ethical judgments are related here to choosing analysis methods, allocating resources, making assumptions on findings, and interpreting them.
3. Decision making refers to the process by which governments adopt a particular course of action or nonaction. On this stage choices between alternative solutions are made by positive or negative decisions or nondecisions. This process allows the preparation of the program as well as clarify the objectives, activities, policy style, and balancing between conflicting objectives. Policy is discussed to be acceptable, legitimated by avoiding bad and doing good. Then adoption of policy is done by law, public programs and strategies, executive orders, rules, and regulations.
4. Policy implementation refers to how governments put policies into effect. Implementation may be organized according to program or may be general and freely structured for policy improvements and flexible actions. Implementation usually includes a series of activities done by variety of policy actors and stakeholders. Here public administrators and servants are confronted with ethical dilemmas about responding to authorities and stakeholders, action according to the professional codes. For example dilemmas may occur when policy goals are too general, when stakeholders are trying to halt or alter implementation, and when different authorities have conflicting expectations.
5. Evaluation refers to the processes by which the results of policies are monitored by state, private, and societal actors, the outcome of which may be reconceptualization of policy problems and solutions. Implemented solutions are evaluated in terms of whether or not they brought the expected results and whether there are any unexpected effects. Policies may not achieve all goals due to ambiguous goals, choosing inadequate action, not taking into account specific conditions, incorrect selection of indicators. Evaluation helps to find reasons why the programs did not respond to the needs of their recipients and explain processes of intervention and outcomes. Ethical dilemmas refer here to choosing appropriate measures, objectively collecting data and interpreting findings. Ethical questions are also posed in responding to stakeholders and deciding on continuing policy, changing it or discontinuing.

Described examples show only some of the possible problems, dilemmas, and ethical decisions which occur in practice of public policy and that may be the subject of further analysis.

Conclusions

Public policy includes directly or indirectly making ethical judgments. Ethical decisions are taken mainly by policy makers by selection and reconciliation of interests represented by individuals, groups, and organizations. Public policy is based on the balancing individual and social values. From those value arise its objectives, principles, and styles of policy implementation and intervention. All choices and decisions in public policy on each stages of policy cycle are ethical judgments because they presuppose that some things are more important than other, that some actions will have positive and other will have negative impact on society. Policy debates can be more productive by using ethical approaches. Ethics enables a systematic analysis of the rules and standards as well as the selection of rational public decisions.

Abstract

The development of public psychiatry and public mental health systems historically have revolved around three main periods: the rise of the asylums, the decline of asylums, and the reform of public mental health systems through new treatments and a new care philosophy. This article presents the most important shifts that shaped public psychiatry during each historical period. The major reforms of the past two decades will also be discussed, with particular focus on some countries as examples of the latest developments in public psychiatry and public mental health systems.

Introduction

Mental health problems account for over 30% of work absences and according to the World Health Organization (WHO, 2004) at least one in four people meet diagnostic criteria for mental disorder at some point in their lives. This trend has been evident in most surveys around the world. Furthermore, the prevalence of mental health problems is more than twice that of physical health problems including cancer and cardiovascular disease. The importance of public mental health to the social, physical, economic, and overall well-being of a society is tremendous. The role of public psychiatry and public mental health systems in society are therefore of crucial importance. The path of evolution of public psychiatry through history and until today has not been an easy one. The field has had to change direction and reconceptualize itself a few times during its development. As will be discussed, the field of public psychiatry is multilayered and is often difficult to define as its involvement with society and public mental health systems encompasses a number of different facets of engagement including public, political, academic, social, and clinical engagement. The evolution of public psychiatry and public mental health systems will be discussed with an emphasis on particular trends and movements that shifted the field along the way and until today.

The Rise of the Asylums

Psychiatry like any medical specialism did not exist before the end of the eighteenth century. However, mental disorder had always been part of humanity and different societies employed different ways of dealing with it. It was most often the case though that mental illness was a family affair as no other systems were in place. In the absence of family support, local communities were in charge of their own facilities and often people with mental illness were sent to jailhouses or any other facilities designed for criminals and people considered disorderly in general.

The Middle Ages

In England, one well-known institution founded as a priory in 1247 was at the Bethlem Hospital (or 'Bedlam' as it became known) in London, which started providing short-term treatment for mental illness a century after it was founded. Thomas Guy within Guy's Hospital in London established one of the first known psychiatric hospitals in 1726 (Murphy, 1991). In the United States, it was not until 1752 that the first hospital for mental health problems opened in Virginia but it was private and it was not until the 1840s that state or public mental health hospitals appeared. During the 1870s, a census of the mentally ill took place in the French-speaking Swiss canton of Fribourg and revealed that a significant number of people with mental illness were kept restrained in unheated rooms and stables. The lack of provision gave rise to the asylum (Murphy, 1991). However, there are some accounts suggesting the existence of psychiatric hospitals in the middle years in many parts of the world including in Islamic countries during the eighth century, in India during the tenth century, and in England during the twelfth century (Howells, 1975). Although such public provision was evident, this was based on archaic and primitive treatments, which are unacceptable in today's standards.

The Renaissance

Organized systematic public mental health systems started appearing during the nineteenth century and asylums started springing up more frequently. In particular, toward the end of the eighteenth century, in many parts of the world and in particular in the United States and Europe there was a notable shift from unregulated provision to the development of mental health systems. Such systems were more centralized and better managed (Rogers and Pilgrim, 2001). During this time and alongside the asylum movement and the subsequent growth of asylums, a new therapeutic movement sprang up in France and Britain, which expanded the focus from care to include cure from mental illness. The movement was based on the doctrine of what was called the 'moral treatment' and was led by a French physician Philippe Pinel (Murphy, 1991). Moral treatment was based on the belief that mental illness is not a biological disease, which was the accepted belief during this time, but that it is caused by psychological factors. Therefore, a cure was possible if patients were cared for utilizing a number of elements such as physical nourishment and care as well as introducing a conversational element to the care by presenting patients with logical arguments. Pinel's doctrine gained a lot of

popularity for the care of people with mental illness in the asylums.

Asylums provided residential care, which could last for a lifetime and hosted a number of illnesses, which during this time would be classified as mental health problems such as dementia, syphilis, learning disability, epilepsy, and even conditions with moral correlates such as single mothers (Porter, 2002). As a consequence, their growth was immense. For example, the United States (during the 1820s and 1830s) and England (i.e., Lunacy Act and County Asylums Act 1845) saw the first pieces of legislation, where it became compulsory for the state government in the United States and local authorities in England to provide public asylums for people with mental health problems. Similar movements were happening at the same time in most developed countries including France, Italy, and the former Soviet Union. Asylums were the main provision of public mental health systems and public psychiatry well into the twentieth century and until after World War II (WWII). It was not until the 1950s when a number of developments started taking place (e.g., antipsychotic medication, care in the community philosophy), which made it possible for a major change, which gave way to the second era in public psychiatry – the decline of the asylum.

The Decline of the Asylum

There were instances during the nineteenth century where thinkers or movements would try and shift the focus of care provision inside the asylums to care provision in the community. These views gained a lot more popularity during WWII. The psychoanalytic school of thought was also gaining popularity in Europe, and Freud's talking therapy was perceived as a good treatment that could replace the asylum system with a system based on community care. During this time, outpatient treatment in the community was a private practice and was not commonplace in public psychiatry. The polemic of two American sociologists, Belknap and Goffman, on the asylums made the criticism to grow larger. In particular, Goffman (1961) described how the asylum environment promoted adverse effects on the treatment of mental illness by removing individual agency, encouraging apathy, withdrawal, and loss of social and personal care skills amongst patients. In 1970, Ervin Goffman became one of the founders of the American Association for the Abolition of the Involuntary Mental Hospitalization, which provided legal aid to psychiatric patients. The growing skepticism toward asylums was helped by the new drug treatments, the rise of psychotherapy, and the deinstitutionalization movement, all of which played a significant role in the decline of the asylums in the 1960s and also gave rise to antipsychiatry. Antipsychiatry was the belief that psychiatric treatments and practices create more damage than good (Burns, 2006). This view gained further popularity through the writings of psychiatrists such as RD Laing, Theodore Lidz, and Silvano Arieti as well as earlier existential philosophers such as Michel Foucault and later psychoanalytic theorists such as Jacques Lacan and Erich Fromm. A common criticism was that more than any other discipline it involves an unequal power between doctor and patient, with the former being able to exercise power in a number of situations including hospitalization, the law and the courts, and norms of normality. Paradoxically, during the decline of the asylums and for the next 30 years the antipsychiatry views were prominent, while the development of public psychiatry and public mental health systems were also prominent.

The Rise of Psychotherapy

Public psychiatry came to the forefront around the time of WWII. Although the idea of the merits of psychoanalysis started appearing toward the last decade of the nineteenth century, it was before WWII that the psychoanalytic school of thought through Sigmund Freud's ideas began to be adopted as a treatment for mental illness (Shorter, 1998). Psychoanalysis also helped further the idea of moving away from the asylums and treating patients in the clinic. The rise of Nazism and other fascist movements around Europe during WWII brought psychoanalysis to a halt and many practitioners moved to America making the treatment popular. The American Psychiatric Association worked in tandem with the American Psychoanalytic Association and soon the majority of members from the former association became members of the latter association too (Shorter, 1998). It needs to be noted though that psychoanalysis as a treatment in psychiatry was very much part of private psychiatry and a very lucrative practice. Nevertheless, the view that the cause of mental illness was not biological, and therefore could be treated with psychoanalysis, paved the way for the decline of the asylums and the new public psychiatry, which was shifting toward providing care in the community.

Advances in Psychiatric Treatments and the Rise of Public Psychiatry

A number of treatments for mental disorders have been used historically. It was mainly during the past 60 years that psychiatric treatments have seen major developments. A controversial treatment called lobotomy was introduced in 1936. The treatment was used to alter mood and regulate disturbed behavior or disturbed thinking by severing connections within the brain. Thousands of these operations took place in Britain and the United States but due to lack of regulations they started declining dramatically toward the end of the 1950s (Bewley, 2008). Electroconvulsive therapy (ECT) was also a common treatment, which was used around the same time and in particular in the beginning of the 1940s. ECT replaced an earlier treatment called convulsive therapy, which was introduced in Hungary in 1934 by a neuropsychiatrist called Ladislas Meduna. Convulsive therapy was based on seizure induction using a circulatory stimulant drug called Metrazol. It was not until 1937 that the first human experiment of seizure induction through electric shocks took place. ECT involved the use of electric currents to induce seizures in order to shift the brain chemistry responsible for mood and/or thought disorders. The use of ECT declined dramatically during the 1960s, but it is still used today to treat severe forms of mental illness (and in particular severe depression), which do not respond to any other treatment. During the early 1950s and after lobotomy and ECT treatments started declining, new treatments became of physiological nature and targeted

glucose levels and the adrenal system through injecting insulin to induce hypoglycemic comas. Insulin shock therapy targeted the adrenal system, which was seen as responsible for mood regulation and in particular as the cause of psychotic disorders (Shives, 2008). The major shift in psychiatric treatments took place in the 1950 and 1960s as the new psychotropic drugs made their appearance. In particular, in 1950 the first anti-psychotic and mood regulatory drugs appeared such as chlorpromazine and lithium, respectively. During the 1960s the rise of talking therapies (e.g., psychotherapy and psychoanalysis) diversified public psychiatry. However, it needs to be noted that the new scientific evidence during the 1970s onwards was a major driver for the rise in public psychiatry, which had seen its popularity dwindling. The new scientific evidence pointed toward the biological basis of mental illness and in particular the 'chemical imbalance' hypothesis for mental illness such as the 'monoamine hypothesis' for depression and the 'dopamine hypothesis' for schizophrenia. The technological advancements of the 1970s allowed for brain imaging techniques to be developed and make these findings possible and paved the way for treatments to have both a physiological/biological basis and a psychological basis.

The Deinstitutionalization Movement

During the 1960s, advances in public psychiatric and other sciences (e.g., social, health and human sciences), drug treatments as well as the emergence of human rights played a significant role in the provision and treatment of mental illness. This brought about the deinstitutionalization movement, which was prominent in many developed countries (Wright, 1997). In England, a number of asylums started closing and in Italy asylums were abolished altogether. It needs to be noted that Italy was the first country in the world to introduce care in the community and it is also a good example of a successful shift from asylum-based to community-based care. Deinstitutionalization also paved the way for new advances in mental healthcare and in particular for the development of community psychiatry, which sought to provide care and support in the community as this was seen a better predictor of recovery from mental illness. Recovery from mental illness and life adjustments were reconceptualized to integrate a number of public mental health systems including medical and psychological treatment and social support. This brought a shift from prior systems, which were focused on short-term hospital-based care (e.g., asylums and psychiatric hospitals) to long-term, ongoing, and sustained support. The deinstitutionalization movement and the subsequent community-based mental health care and services took place in a number of countries of varying economic development. Following Italy, United States, England, Australia, New Zealand, and the Scandinavian countries were amongst the first countries to implement community-based mental health care.

During and Post-Deinstitutionalization

The deinstitutionalization movement, which was particularly active during the 1970s onwards, reformed public mental health care systems. Such systems, which developed around the world, revolved mainly around providing supporting housing, very often with supervision of care workers on the premises as well as community mental health teams. Such teams comprised a group of specialists including psychiatrists, psychologists, occupational/vocational workers, substance abuse specialists, social workers, and psychiatric nurses. The aim of these teams was to enhance independence, recovery, and rehabilitation and therefore, prevent the negative impact of severe mental illness such as homelessness, substance abuse, hospitalization, and any other negative consequences that arise from mental illness. Examples of community teams around the world included the assertive community treatment (ACT) teams in the United States and the early intervention teams in the United Kingdom. In particular, during the 1970s, ACT became the predominant model adopted by public mental health systems. It was first used in a state psychiatric hospital in Madison, Wisconsin and since then it was replicated and was applied widely within the United States as well as in a number of countries around the world including Australia, Canada, and the United Kingdom.

In the 30 years and until the late 1990s, psychiatric hospitals closed rapidly. However, the closure of hospitals was not accompanied by a surge of provision in community care. This resulted in a lack of suitable provision. The lack of suitable provision with an additional lack of suitable governance and coordination failed to provide patients with the desired social integration. As a consequence, public mental health systems failed to deliver integration of psychiatric patients in the community and provide care for a complexity of needs. Patients were very often discharged too early without suitable post-hospital provisions, were very often marginalized in sheltered environments, and a great deal of patients ended up homeless or in prisons (Fakhourya and Priebe, 2007). A number of new policies were introduced around the world throughout the 1970s and 1980s in order to shape public mental health systems further and provide appropriate social integration to patients with mental health problems. However, the main issue of how to provide social integration was still evident because community services alone could not care for a multiple of needs. For public mental health systems to work effectively, a psychiatric and/or discharged patient needed to have a strong social network (e.g., friends, family), which very often was not the case.

Public Psychiatry and Psychiatric Rehabilitation

The failure of public mental health systems during the deinstitutionalization movement to provide effective care in the community gave rise during the 1980s to the reconceptualization and refinement of service systems. This resulted in the development of the concept of psychiatric rehabilitation. The emphasis was on the treatment and management of the consequences of mental illness and not on the illness. Public mental health systems were reconceptualized to include a number of elements such as treatment, crisis intervention, case management, rehabilitation, enrichment of activities, rights protection, basic support, and self-help. The World Health Organization developed a model of psychiatric rehabilitation by conceptualizing how severe mental illness affects people's lives (see **Box 1**).

Box 1 The psychiatric rehabilitation model

The stages of the impact of severe mental illness:

- Impairment (e.g., hallucinations)
- Dysfunction (e.g., lack of vocational and social skills)
- Disability (e.g., unemployment)
- Disadvantage (e.g., poverty, discrimination, stigmatization)

By conceptualizing the different stages that severe mental illness impacts on, the overarching aim was to provide patients with help to achieve illness management as well as social and vocational skills. Interestingly, psychiatrists and public psychiatry generally were largely pushed away from shaping up and providing psychiatric rehabilitation. This was partly because of the rising of antipsychiatry feelings amongst service users and part of this was a result from the failed promises of the deinstitutionalization movement. Psychiatrists also found themselves as part of multidisciplinary teams with a role that was often unclear and undefined. For example, public mental health authorities were often utilizing other specialists in providing medical treatments, and psychiatrists were seen as unsuitable in providing patients with the necessary skills for social and vocational integration.

The Reform of Public Psychiatry and Public Mental Health Systems in the Past 20 Years

The deinstitutionalization movement brought a number of policy changes from the 1960s onwards and shaped public psychiatry further. More recently, international and European policy was also introduced such as the United Nation's "Principles for the Protection of Persons With Mental Illness and the Improvement of Mental health Care" in 1991 and "The Charter of Fundamental Rights of the European Union" in 2000, both of which emphasized the need for community care for people with mental health problems (Knapp et al., 2011). The problems in the implementation of care in the community of the past 50 years pushed the policy agenda further and introduced the idea that people with mental illness need more than symptom management and relief. This brought about the latest developments in public psychiatry and public mental health systems, which revolved around the concept of recovery and the so-called 'third wave' of psychological treatments (e.g., cognitive behavioral therapy).

Recovery Movement

In the early 1990s and as asylums continued closing, the recovery movement started gaining popularity, especially amongst service users. The recovery movement became popular both in the United States and Europe and underlined the need to shift the focus from symptom management and service use to indicators of well-being and service user empowerment. Public mental health systems acknowledged that people with mental illness have multiple needs such as social (including removing the stigma attached to mental illness), vocational, residential, educational, etc., which cannot be met through hospitalization or by just treating illness symptoms (Anthony, 1993). Although the identification of these needs (e.g., vocational, residential, social rehabilitation) was not new, the recovery movement added a new dimension to the conceptualization of these needs. The movement realigned the relationship between public psychiatry and service users and emphasized the role of the latter in being responsible both for having control over their treatment plan and for their own recovery process. The concept of recovery within public mental health systems is not fully researched and therefore its application is still under investigation. Following the care in the community and the recovery movement, it is a common process in many countries for service users along with their families to influence their treatment and recovery process by being involved in the decision-making process.

Latest Initiatives in Public Psychiatry and Public Mental Health Systems

The past decade has also seen a number of further initiatives in public psychiatry and public mental health systems across the world. WHO (2007) outlined the need to further develop public or community-based mental health systems based around a number of key components (see **Box 2**).

A review of public mental health systems around the world through data collected by international organizations and published country profiles was developed by WHO (2009). According to the report, most countries and in particular middle- and low-income countries do not offer adequate mental health care. For example, approximately 28% of countries have a budget for public mental health care, many countries have notable shortages of staff in mental health-related services and many systems still rely on psychiatric hospitals for care provision. Nevertheless, the last decade has seen the emergence of a number of major initiatives in the area of public psychiatry to reform public mental health systems further. Looking at some country examples, it is evident that public psychiatry today involves a number of activities and roles extending from providing a wide range of treatments for mental health problems to educating the public, designing stigma reduction campaigns and programs, working closely

Box 2 Key components of public mental health systems (WHO, 2007)

Key components of public mental health systems:

- Enable the provision treatment for mental illness in primary care
- Enable wide access to psychotropic medication
- Enable the provision of care in the community
- Educate the public (e.g., remove the stigma of mental illness)
- Incorporate communities, families, and service users in decision-making
- Develop mental health-related policies, programs, and legislation
- Develop human resources and create links with other sectors
- Support research- and evidence-based practice and monitor public mental health

with the government and the charity sector to influence policies and legislation, as well as working closely with patients and carers. Examples of such initiatives can be seen through the latest public health system reforms in the United States and the United Kingdom.

Recent Examples of Public Mental Health System Reforms: the United States and England

In recent years in the United States some leading professional bodies in the field of psychiatry such as the American Association of Community Psychiatrists (AACP), the National Council on Community Behavioral Healthcare, and the Community Behavioral Health Organization, to name a few, have driven the development of public psychiatry and public mental health systems. For example, members of the AACP developed the Psychiatric Leadership Development Program in 2007, which aims at providing further training for psychiatrists. Training involves enhancing knowledge of public mental health systems and skills in psychiatric-related administration as well as coaching psychiatrists in organizational leadership. Similarly, in 2008 AACP developed a new set of guidelines for developing advanced postgraduate training fellowships in public and community psychiatry. The elements of the fellowships were divided into core elements, which included academic, research, teaching, clinical work, and staff supervision elements and elective ones, which included systems management, community advocacy, recovery-oriented services, and cultural competence. Since AACP developed these guidelines there have been a growing number of US universities providing training in public psychiatry.

Similar activity has been taking place in England. In particular, the National Service Framework for Mental Health (NSF-MH) was published by the Department of Health in 1999 setting a 10-year plan for reform in public mental health systems. Since then the NSF-MH has been refined and extended to include additional policy documents and guidelines from the National Institute for Health and Care Excellence (NICE). The aims of the report were structured around seven standards, which public mental health systems needed to incorporate. These standards also cover funding, service provision, and staffing. The specifications covered the whole spectrum of public mental health provision including both hospital- and community-based care as well as services of both primary and specialist care. The guidance also aimed at (1) program development to reduce stigma and discrimination associated with mental health and (2) improving access to mental health services. As part of the NICE guidance, the Improving Access to Psychological Therapies (IAPT) program was launched in 2005 and aimed to improve access to treatment for depression and anxiety. The aim was to increase well-being amongst the working population and reduce the cost of providing incapacity benefits. When IAPT was first launched, it only provided cognitive behavioral therapy to the working age population but since then it has increased its accessibility to all age groups as well as its availability of therapies. Additional therapies include counseling, couple counseling, dynamic interpersonal therapy and interpersonal psychotherapy. This brought further reforms to public psychiatry as IAPT services require and provide training in psychological therapies, which traditionally were not part of the psychiatric training.

The Future

The latest initiatives in public psychiatry and the subsequent reforms in public mental health systems suggest that the field has been going through significant reconceptualization and has become a lot more multifaceted encompassing public, political, and social engagement. As a consequence, there is some lack of clarity with regards to how public psychiatry can promote the interaction of all these different facets and/or how these facets fit into the role of a public psychiatrist. It seems plausible to suggest that in the next decade public psychiatry will be adding clarity and defining its boundaries and place in the field of mental health further. Furthermore, the progress of the past decade in public psychiatry suggests that there is a variety of new training opportunities (e.g., psychotherapies, governance, management, public engagement, etc.), which expand beyond the psychiatric training received during specialization. This will help public psychiatry to fulfill the expectation of a multifaceted field, which has a significant role to play in society and which extends beyond the clinic and/or the academia.

Abstract

This article discusses various theories of, and problems for, publicly shared reasons and reasoning. The Enlightenment ideal that a common basis of reasoning, such as scientific method, faces a number of modern challenges that are discussed. These challenges include those of cultural diversity, the view in philosophy of science that different epistemic values must be weighed as the data always underdetermines theory, and the reasonable moral pluralism that arises from what Rawls calls the 'burdens of judgment.' Attempts discussed include appeal to common core of epistemic norms, the prerequisites of mutual understanding, shared liberal-democratic commitments, and convergence on social norms with diverse justifications.

Theories of public reason are responses to a distinctively modern worry: that the free use of human reason, rather then producing consensus in belief and moral conviction, leads to disagreement and conflict. The worry stems from a variety of sources: social science, the philosophy of science, and the moral pluralism of modern societies. This article begins by examining the lines of inquiry that have led many to question whether all fully informed and fully competent inquirers would come to the same conclusions about science and morals. According to some philosophers and social scientists, the very concept of reason has broken apart, leaving different individuals and groups with different conceptions of rationality, and so of reasons for belief and action. The article then considers the different ideals of public reason that have been advanced to overcome worries about the 'fragmentation of reason.'

The Diversity of Reason

The Enlightenment

According to the conception of reasoning that dominated the European Enlightenment of the seventeenth and eighteenth centuries, reason is inherently universal, and so shared and public. On this Enlightenment conception, reason is a shared capacity of all human beings, and norms of good reasoning are universal. Any premise p that is true for one person is necessarily true for all others; if the inferential rule '$(p\&(p\rightarrow q))\rightarrow q$' is valid for one person, it is necessarily valid for all. The true and valid results of one person's reasoning are necessarily true and valid for all. According to this standard Enlightenment view, the use of common human reason produces consensus not only on scientific beliefs, but also on moral and political opinions. To be sure, people might disagree on matters of science or ethics, but that would be due to mistaken beliefs or irrationality: some have arrived at the wrong answer. The process of Enlightenment was the only remedy for this – the increasingly better use of reason to uncover truths about the natural and the social world. The ideal or model was that of Newtonian physics: just as our common reason had uncovered the laws of matter and motion, so too could it be expected to uncover the laws of human nature, society, morals, and politics. Each field was awaiting its Newton.

Relativism and Social Science

It is a familiar story how the systematic study of cultures with radically different norms from those of Europe gave rise to cultural relativism. When confronted with the very different mores of the Zuñi and Kwakiutl Indians and Dobu Islanders of Papua New Guinea, Ruth Benedict (1934) endorsed a relativistic view – their norms were justified for them, just as Western norms were for Europeans. As anthropologists began to study non-European cultures in more depth, and became increasingly more sophisticated and self-reflective in their techniques, disputes arose about the proper method for anthropologists to interpret the belief systems of other cultures. For example, was a belief in magic or a deity to be understood as simply a false belief on which the 'natives' relied? John Stuart Mill (1974[1843]: pp. 766–767) believed that an investigator could best understand the magical beliefs of other cultures by attributing to them erroneous beliefs and invalid inferential rules. Others, adopting a principle of charity, have insisted that the best interpretation of a culture minimizes the number of false beliefs attributed to its members (Davidson, 1973). Thus the best interpretation – which makes sense of the 'native's' metaphysical theories, religious convictions, and their beliefs about nature – might seek to show that a belief in spirits is, after all, rational given their world view. Thus, the second step in the relativist attack on the Enlightenment's ideal of reason was to endorse relativism concerning what beliefs are rational in different cultures. The last step in the relativistic project was to apply tolerance to the idea of reason itself. Can Western anthropologists properly interpret other cultures if they apply their Western conception of reason in their interpretation? Is the very idea of reason culturally relative?

Pluralism and Indeterminancy

Social science thus provided one source of the 'fragmentation of reason.' Of course, there was, and still is, lively debate within social scientific and philosophical circles about whether any such relativistic view of reasoning is justified, and if so to what extent individuals employ different, but equally good, norms of reasoning. Nevertheless, some form of cognitive relativism is widely accepted. Concurrently, developments in the philosophy of science were challenging the idea of common, human,

reasoning in the very citadel of the Enlightenment – science itself. Whatever doubts may be entertained about the application of Western reason to other cultures, or departures from expert norms by ordinary reasoners, surely science is still the model of rational discourse tending to convergence of opinion leading to the truth. To many, Thomas Kuhn's analysis of scientific practice demonstrated that, rather than a shared project of pursuit of the truth, judged by rules of reason held by all, scientific inquiry takes place within 'paradigms' that determine not only what constitutes research problems but what constitutes success in a research program. Within a group of scholars sharing a paradigm, the Enlightenment's ideal of common norms of reason and consensus on the truth will be approximated; and insofar as 'normal science' is dominated by a single paradigm in each field, there often is a common mode of reasoning. But in times of scientific crisis, when paradigms compete, some have insisted that there is no rational, impartial way to adjudicate among the competing theories.

The crux of Kuhn's analysis is that because data underdetermines theories, scientists draw on values in adjudicating among theories. "To a greater extent than other sorts of components of the disciplinary matrix," writes Kuhn, "values may be shared by men who differ in their application. Judgments of accuracy are relatively, though not entirely, stable from one time to another and from one member to another in a particular group. But judgments of simplicity, consistency, plausibility, and so on often vary greatly from individual to individual … Even more important, in those situations where values must be applied, different values, taken alone, would often dictate different choices. One theory may be more accurate but less consistent or plausible than another" (Kuhn, 1970: p. 185). The crucial claim is that there is no uniquely rational way to order these various desiderata – simplicity, consistency, plausibility – and different orderings endorse different scientific theories upholding competing truth claims. Equally well-informed scientists employing their reasoning in perfectly legitimate ways can arrive at different judgments about what is true. Fred D'Agostino (1996, 2003) generalized the analysis. In any field of inquiry, when there exists both a plurality of criteria and no impartial way to order the criteria, the criteria are apt to be indeterminate in their application. Different orderings produce different outcomes – reasons for belief. According to D'Agostino, the criteria only yield a determinate result when an ordering is provided, but impartial reason cannot give us that. Much of postmodernism is based on this key idea. Reason is inherently perspectival because of the inherent plurality of relevant considerations for which there is no rational, impartial ranking.

Reasonable Pluralism

Kuhn's analysis of scientific practice and D'Agostino's generalization rely on the idea of indeterminancy: reason underdetermines choice between various theories and perspectives. A more modest view maintains that our powers of reasoning are inconclusive on many complex matters of science, morality, and politics. Claim C is characterized by reasonable pluralism if some perfectly reasonable agents do, while others do not, have good reasons for accepting C. For a controversy to be characterized by reasonable pluralism, it is not simply the case that people actually disagree about the merits of C, but that it is reasonable for one person to assert C and another not-C. This is a far less radical claim than was examined in the last section: it is not argued that the question 'C or not-C?' is inherently indeterminate but only that present beliefs about C are inconclusively justified. According to John Rawls, our disputes about value seem subject to reasonable disagreement because our understanding of what is good and valuable is especially subject to what he has called the 'burdens of judgment.' According to Rawls, reasonable judgments so often are at odds because

1. the evidence is often conflicting and difficult to evaluate;
2. (as in Kuhn's example) even when we agree on the relevant considerations, we often weigh them differently;
3. because our concepts are vague, we must rely on interpretations that are often controversial;
4. the manner in which we evaluate evidence and rank considerations seems to some extent the function of our total life experiences, which of course differ;
5. because different sides of an issue rely on different types of normative considerations, it is often hard to assess their relative merits;
6. in conflicts between values, there often seems to be no uniquely correct answer (Rawls, 1993: p. 57).

Because these matters are so complex and uncertain, different people will reach different, competing, credible, or reasonable conclusions. In the face of complexity, our powers of reasoning do not produce convergence.

Conceptions of Public Reason

Public Rationality and Public Reasons

Important movements in social science, the philosophy of science, and moral and political philosophies thus have combined to cast grave doubt on the Enlightenment's confidence that the free exercise of human reason leads us to agree. In the face of these challenges to the ideal of common human reason, theories of distinctly public reason have been advanced to show how people can share reasons (Korsgaard, 1996: Chap. 10). However, this idea is ambiguous. It may constitute a response to relativistic social science (see Section Relativism and Social Science), which challenges the very idea of a shared conception of human reason. Understood thus, the ideal of public reason is an ideal of public rationality, or a shared conception of rationality. The challenge posed by reasonable pluralism (see Section Reasonable Pluralism) is more modest. Advocates of reasonable pluralism maintain that even if we apply shared standards of reason, our deliberations will not yield shared reasons for belief. In a weaker sense, then, the ideal of public reason is an ideal of public reasons, or how we can arrive at shared reasons to believe and act. A theory of public reason may advance a theory of public rationality and/or public reasons.

Four main conceptions of public reason stand out: (1) epistemic, (2) shared practice, (3) political, and (4) convergence.

Epistemic Theories of Public Reason

In philosophy, 'epistemology' refers to the theory of knowledge or, more broadly, the theory of justified belief. Epistemic

theories of public rationality, then, maintain that at least some common norms of reasoning can be justified to everyone. The Enlightenment view was that all valid norms of reasoning can be justified to everyone – reason was inherently public. Epistemic theories of public rationality need not, however, advance such a sweeping claim. Importantly, an epistemic theory of public rationality may adopt a modest version of the 'relativism of reasons' (see Section Relativism and Social Science), according to which in some cases person Alpha may have a fully justified norm of reasoning N while Beta accepts a fully justified norm of reasoning M, where it is the case that N and M are inconsistent. In cases where only N and M are relevant to deliberation, a relativism of rationality will manifest itself; Alpha may have reasons based on N that Beta will deny on the basis of M, and both will be justified. However, to establish a thoroughgoing relativism of reasoning that undermines the possibility of public reason, it is not enough to establish that this can sometimes occur; it must be shown that no common norms of rationality can be justified to all – that it is always (or at least usually) the case that for any justified norm of reasoning held by Alpha, some person Beta will be justified in accepting a competing norm. That is the sweeping relativistic claim rejected by epistemic theories of public rationality (Gaus, 1996).

In reply to the anthropological argument (see Section Relativism and Social Science), epistemic theorists of public reason can embrace Martin Hollis' view that an anthropologist must build up an interpretation of an alien language by locating a 'bridgehead.' The assumption underlying the bridgehead strategy is that others generally perceive what we perceive and tend to say about it the sorts of things we would say. Relying on these assumptions, the anthropologist begins by translating everyday, basic perceptual sentences such as 'Yes, this is a brown cow' and 'No, it is not raining right now.' Now, Hollis insists, this bridgehead not only includes translations of such basic beliefs, but basic logical rules, since "what a sentence means depends on how the beliefs which they express are connected, and that to justify a claim to have identified a belief one must show the belief is connected to others." The point, then, is that the context that sets the stage for the possibility of relativism – that we confront others, different from us but of whom we can make some sense – presupposes widespread shared norms of inference as well as beliefs. Thus, the very possibility of mutual intelligibility sets a limit on the extent to which we can understand others as employing cognitive processes different from our own.

Shared Practice Theories of Public Reason

Epistemic accounts of public reason uphold our ability to reason together because they insist that we do, indeed must, share basic rules of inference. In contrast, shared practice accounts of public reason conceive it as arising out of a shared social life and/or shared discourse (*see* Shared Belief: Philosophical Aspects). A number of otherwise diverse philosophers such as Ludwig Wittgenstein, Jürgen Habermas, Richard Rorty, Susan Hurley, and Philip Pettit all point to the idea that reasoning is a social phenomenon. In order to be a deliberator, one must be a member of a community in which one's beliefs and rules are intelligible to others. One comes to understand what is a justified or unjustified belief, and what is a good or a bad way of reasoning, by sharing the norms and standards of communities, including communities of inquirers. Thus, some insist that "ultimately, there is only one criterion by which beliefs can be judged valid, and that is that they are based on agreement reached by argumentation" – we converge on them (this is Habermas's (1990: p. 14) gloss on Rorty's 'particular version of discourse theory'). Habermas draws an intimate connection between mutual understanding (*Verständingung*) and agreement (*Einverständnis*). It would seem that to understand others one must in some way arrive at intersubjective agreement about norms of rationality and good reasons. Consequently, the phrase 'public reason' becomes almost redundant: something can only be identified as reason because it is the object of public, interpersonal, agreement.

Wittgenstein and his contemporary followers such as Hurley (1989) and Pettit (1993) suggest a broadly similar view. Reasoning itself presupposes a 'community' – common rules of thought. Wittgenstein (1958) argued that one could not have a private rule that one only followed once – for in such a case we could not know whether the rule was actually followed. More generally, it has been argued that one cannot have a purely private rule, for one needs to be able to distinguish when one has correctly followed the rule and when one has gotten it wrong. But, assert Wittgensteinians, the difference between correct and incorrect applications of a rule cannot be located in individual belief systems, but only by the individual comparing one's application of the rule to those of one's fellows: each must look to others to check and correct his or her rule-based performances. Since thinking is necessarily rule driven, the analysis applies to reason itself. Thus, it seems that the very idea of rule following – and, so, of reasoning – supposes agreement with others. If so, the search for reason is a search for agreement.

In one respect, this view, somewhat surprisingly perhaps, returns to the basic idea of the Enlightenment – all reason is public reason. The Enlightenment was confident in asserting this because of the widespread faith in a universal, common, human faculty of reason that could accurately represent reality, whereas shared practice theorists see reason as arising out of a shared public life. To put it crudely, rather than reason producing agreement, agreement generates reason. Thus, the publicness of such reason, unlike that of the Enlightenment's, is consistent with a cultural relativistic conception of rationality. The public, intersubjective agreement, reached by one culture – which is constitutive of their very conception of rationality – may be very different from that upheld by another.

Because shared practice accounts of public reason stress the constitutive nature of public agreement to the very idea of reason, and because public agreement may be promoted by political institutions, more radical shared practice theorists such as D'Agostino give political institutions a constitutive role in determining what reason is (1996: Chap. 9). This is a radical view indeed – however, it is not entirely novel, perhaps going back as far as Hobbes. For Hobbes (1948[1651]), the conflict in the state of nature arises from conflicting private judgments; people's private reasoning yields conflicting judgments of right and wrong, as well as matters of fact, and

this leads to the less intellectual conflict that characterizes the state of nature. Hobbes's solution is to appoint an 'arbitrator.' This 'judge,' says Hobbes, provides 'public reason' to which private reason 'must submit.' The arbitrator proclaims what each has reason to do, and so defines a single, coherent conception of reason. Because, in Hobbes' view, we have authorized the judge (i.e., sovereign) to define public reason for us, the sovereign's pronouncements constitute a shared public reason on which there is agreement.

Public Reason qua Political Reason

D'Agostino's radical view allows the political to shape the rational. A more modest proposal with which this radical view is easily confused maintains that the notion of public reason is a purely political idea, in the sense that it concerns only how we reason together about politics. This understanding of public reasons lies at the heart of what is commonly known as 'political liberalism.'

Rawls's political liberalism is a response to the problem posed by reasonable pluralism (see Section Reasonable Pluralism). For Rawls, the crucial problem is that citizens in democratic societies entertain a plurality of what he calls reasonable 'comprehensive doctrines' – overall philosophies of life centered on religious, philosophical, or moral beliefs. This pluralism seems a permanent feature of modern societies. "Political liberalism assumes that, for political purposes, a plurality of reasonable yet incompatible comprehensive doctrines is the normal result of the exercise of human reason within the framework of free institutions of a constitutional regime" (Rawls, 1993: p. xvi). The reasonable pluralism of comprehensive views renders such views unacceptable as bases for the justification of political power. Rawls endorses the 'liberal principle of legitimacy,' that is, that "our exercise of political power is fully proper only when it is exercised in accordance with a constitution the essentials of which all citizens as free and equal may be reasonably expected to endorse in the light of principles and ideals acceptable to their common human reason" (p. 137). Thus, because there exists a reasonable plurality of comprehensive doctrines, basing the justification of political power on any of them violates the liberal principle of legitimacy. This leads Rawls to seek a political conception that 'all affirm' and that is 'shared by everyone.' Such a conception would be supported by the diverse reasonable comprehensive doctrines that characterize our democratic societies. It would generate public reasons that would fit into our many reasonable, but irreconcilable, comprehensive views. Some version of the principle of political legitimacy motivates the search for public reasons in contemporary liberal political philosophy: if the exercise of coercive political power relies on nonpublic reasoning, it is oppressive and illegitimate in relation to those who do not share those reasons.

Rawls's core argument – and so his entire political liberalism – apparently depends on the contrast between comprehensive views and the shared, political conception. Comprehensive conceptions produce diverse reasons that conflict, whereas the political point of view provides public reasons – reasons that all reasonable comprehensive views can endorse.

Habermas (1995) suggests that Rawls posits an 'a priori' distinction between the political and nonpolitical spheres. At least at times, Rawls seems to suggest that the political point of view can be conceptually distinguished from moral, religious, and philosophical matters; the former identifies a common point of view that can be affirmed by all, whereas when human reason is applied to moral, religious, and philosophical issues, it leads to reasonable disagreement. It is difficult, however, to accept the claim that some single conception of the political is shared by all reasonable persons in modern democratic societies. Political theorists have often pointed to the 'political' as an 'essentially contested' concept – one that is open to divergent, reasonable interpretations (Connolly, 1983: Chap. 1). If citizens of modern democratic societies disagree about the concept of the political, it cannot serve the function of identifying public reasons that overcome reasonable pluralism. Like the moral and philosophical, the nature of the political itself seems a matter of reasonable disagreement.

An alternative interpretation of Rawls' view is to take the political conception as constructed out of that which is shared. On this reading, the nonpolitical is, by definition, those matters on which the free use of reason by citizens in democratic societies leads to different, reasonable conclusions. It is, by its very nature, the realm of reasonable pluralism. In contrast, one might define the political as those matters on which reason converges in democratic societies, and so necessarily generates constitutional principles that satisfy the principle of liberal legitimacy. The political is thus characterized as the overlapping consensus of those diverse comprehensive views characterizing modern societies. The problem for this interpretation is that Rawls himself indicates that the free use of human reason leads us to reasonable disagreement about conceptions of justice and constitutional essentials. The 'political' qua 'shared perspective' is limited to the abstract concept of a 'liberal political order' (Rawls, 1993: p. 241). "By this [Rawls says] I mean three things: first, it specifies certain basic rights, liberties, and opportunities (of the kind familiar from constitutional democratic regimes); second, it assigns a special priority to these rights, liberties and opportunities, especially with respect to claims of the general good and of perfectionist values; and third, it affirms measures assuring all citizens' adequate all-purpose means to make effective use of their basic liberties and opportunities" (p. 223). Thus stated, the content of public reason seems sparse indeed. Unfortunately, if a more detailed articulation of this idea is provided, Rawls indicates that the use of human reason again leads to disagreement. Apparently, modern democratic societies agree on only the most abstract of public – political – reasons.

Convergence Accounts

We have thus far supposed that public reasons are shared or common reasons. Following D'Agostino (1996: pp. 30–31), Vallier (2011) contrasts this 'shared' or 'consensus' view to a 'convergence' conception. According to public reason qua convergence, Alpha and Beta may endorse common conclusions for different reasons; the conclusion is vindicated by public reason because each person has some sufficient reason for it from the perspective of his or her distinctive

commitments. For example, the separation of church and state is supported by some secularists because they do not want the state promoting religion, and also by the religious with doctrines of free faith or who fear the corruption of religion by politics. The key is that the reasoning of different members of the public may converge on some principles, rules, laws, or policies even if they lack consensus regarding why those principles, etc., are appropriate.

To advocates such as Vallier, convergence holds out the possibility of commonly endorsed rules and laws in a social world in which we deeply disagree about the sources of normative justification. For the convergence theorist, our differences are not simply obstacles to, but resources for, achieving a public perspective. However, many reject the idea of convergent public reason.

Jonathan Quong argues that it valorizes a type of insincerity (cf. Larmore, 1996: pp. 134–135; Macedo, 1995; Schwartzman, 2011). Convergence allows Alpha to offer consideration *C* to Beta to justify law *L* because Beta accepts *C*, although Alpha himself thinks *C* quite misguided. But offering as 'reasons,' considerations one rejects may seem like mere rhetoric or manipulation. Quong insists that only shared reasons can ground each seeing the other as having good reason, and thus as truly justified in endorsing *L* (2011: pp. 265ff). Quong's argument here depends upon holding that Alpha can see Beta as justified in holding views that he or she rejects. If, however, Alpha accepts the sources of the diversity of reason and reasoning we canvassed above (see Section The Diversity of Reason), he or she is apt to reject the deep assumption of Quong's critique: that what are good reasons for Alpha must be what are good reasons for Beta (Gaus, 1990: Part 1; Gaus, 1996: Part 1; Gaus, 2010: Sect. 13).

Convergence theorists not only defend convergence reasoning as compatible with respectful engagement, but also seek to turn the tables on their critics, arguing that the demand for consensus is what fails to respect diverse individuals. Jeffrey Stout argues that an alternative to the retreat to a common ground is a Socratic dialogue, in which I show you my reasons and you show me yours, or, more fully, employing the mixed "strategy of expressing one's own (perhaps idiosyncratic) reasons for a political policy while also directing fair-minded, nonmanipulative, sincere immanent criticism against one's opponent's reasons" (Stout, 2004: p. 85). Furthermore, respecting people in light of reasonable pluralism may require taking their diverse comprehensive views seriously instead of prohibiting appeal to them (see Vallier, 2011: pp. 264, 273; Stout, 2004: p. 73).

It must be noted that convergence reasoning dissolves the Enlightenment target of the best principles of justice and public policies. As A. Sen argues, members of the public with diverse perspectives rarely converge upon judgments about the best principles and policies, but will often agree to a broader set of policies worth endorsing (2002: Chap. 4). Consider Alpha who believes there are special obligations to the poor because of his or her religious belief and Beta who believes that preventing the desperation of severe poverty reduces crime. Alpha and Beta likely find many poverty-relief polices worth supporting and better than the injustice of having no such policy, although they disagree about which is best. They each can compromise to accept a policy that promotes, without maximizing, his or her values. Convergence provides a set of eligible policies within which public reason is inconclusive. The legitimacy of a particular policy within this eligible set requires use of a political decision procedure (Gaus, 1996: Part III) or appeal to the existing, partially contingent, status quo (Gaus, 2010: Sect. 21). Convergence reasoning thus significantly reinterprets, or moves beyond, the Enlightenment ideal.

Membership in the Public

Members of the public are those whose perspectives must be accounted for in public reason. Since public reason accounts arise from recognition of reasonable pluralism, membership to the public cannot be restricted to believers in 'the Truth.' If we had an independently defined truth, we may want to investigate what sort of people would understand and believe it, or what reasoning capacities facilitate discovering that truth. Public reason, however, treats the public as an independent variable while searching for the conclusions such a public could endorse.

The members must be picked out by criteria at least some of which are independent of the conclusions they support. Epistemic theories (see Section Epistemic Theories of Public Reason), for instance, provide basic features of rational thought that anyone must follow to count as a member of the public. This requirement will rule out some conclusions, such as contradictions, but does so without narrowing the public to a single perspective. Membership may also require moral capacities, such as Rawls's requirement that members not only be rational, but also have an interest in forming, and ability to comply with, fair terms of cooperation. Moral restrictions may be very basic, such as simply excluding psychopaths and others lacking developed moral emotions (Gaus, 1990: Sect. 17). Some theorists, on the other hand, argue that particular substantive commitments are necessary, excluding perspectives that do not give sufficient priority to democratic equality or other values. Requiring these value commitments may seem necessary to ensure that our political principles are not 'held hostage' by the demand of immoral "or otherwise troublesome people in the world as we know it …" (Quong, 2011: p. 37). The justification of even basic liberal rights could be at stake if the public includes those with highly illiberal values. It is hard to see, however, why the conclusions of public reason with a value-restricted membership should be authoritative over people with dissenting values. From the dissenting perspective, the 'public' conclusions will appear to be sectarian and merely authoritarian impositions. An important alternative to value-based exclusions is to find shared presuppositions, such as the conception of ourselves as agent, from which public reason can craft liberal principles (Gaus, 2010: Chap. VI). People not sharing such a conception are outside the public not for being immoral or troublesome, but instead because they would seem to not be persons at all and their perspective is too distant to form a public with us.

Conclusion: Reasoning in a Plural Society

Puzzles about the possibility of shared, public rationality and reasons derive from a variety of sources: social science, the

philosophy of science, and the moral pluralism of modern societies. Although developments in all these fields serve to cast doubt on the Enlightenment's ideal of a common universal reason, they pose different challenges. The ideal of public reason is as diverse as the sources of our doubts about the possibility of shared ways of reasoning in contemporary societies. In all its manifestations, however, the ideal of public reason seeks to maintain the heritage of the Enlightenment – the free use of human reason will lead us to agreement in our public life.

Abstract

New public management-inspired reforms created numerous autonomous units with many different faces and labels. This variety of organizations and organizational forms precludes a straightforward definition of what constitutes a public sector organization and blurs the boundaries between the public and private sectors as well as the boundaries of single organizations. In addition, the complexity of the interlocking arrangements and relationships in this public organizational landscape has resulted in considerable governance problems with serious implications for coordination and policy coherence.

Modern society is a society of organizations and this is also true for the public sector where organizations have become the central building blocks of states: Public services are delivered by organizations; organizations monitor compliance with legal requirements, regulate liberalized public services, or manage the distribution of public funding. This ubiquity of organizations has been observed by many scholars in the field: Terms like 'para-government organizations' (Hood and Schuppert, 1990), 'agencification' (Pollitt et al., 2001), 'quangocratization' (Hood, 1986), or 'corporatization' (Ducan and Bollard, 1992) emphasize the relevance and heterogeneity of organizations in the public sector. Moreover, observations that citizens are "now separated from their representatives by an asteroid belt of organizations" (Barley, 2007: p. 202) and that the current "arrangements raise questions of considerable constitutional and political significance, including the possibility of state sovereignty being diffused" (Thynne, 2003: p. 318) give evidence of the concerns connected with their proliferation. Brunsson and Sahlin-Anderson (2000) have argued that the public sector reforms of the 1980s and 1990s can indeed be summarized as turning public services into organizations. These far-reaching transformations of the architecture of states seem to have converted public sector reforms into organizational change processes.

Despite their ubiquity, the question of what defines a public sector organization (PSO) is far from easy to answer. What is the distinctive nature of a PSO besides the very general observation that it is an entity located in the diffuse "sphere of delegated governance" (Flinders and Skelcher, 2012: 330) of the state? Is it their ownership structure, the task they perform, their legal form? What is the appropriate level of attention: The individual organizations or the whole network of organizations? Today, not least due to the developments of the past three decades, there is no typical organizational form that encompasses all PSOs and no single classification that captures their diversity. To use Hood's (1986) metaphor: PSOs are not a particular animal or even species, they make up a whole administrative zoo. Apart from this heterogeneity in form, PSOs exist in ambiguous contexts. While, on the one hand, individual PSOs are often very stable, inflexible, and in some cases even immortal (Kaufman, 1976); on the other hand, they exist in a field which is highly dynamic and subject to ongoing change and intense reform activities.

We will, in the following, first outline the developments that have contributed to the increase in numbers, variety, and relevance of PSOs. We then discuss shifts in the various types of activities these organizations perform. In order to give an overview of the heterogeneity of organizational forms in the public sector and the current discussion, we briefly review different criteria used for classification and point to the blurring of sector and organizational boundaries that has been a result of the organizational pluralism. Finally, we address the consequences for governing this heterogeneous organizational landscape and close with a short conclusion.

New Public Management Reforms and Public Sector Organizations

Reform per se is, as Mayntz (1997) remarked, a permanent reflex of administrative praxis. The past three decades have certainly been no exception from this general observation. During this time, the public sectors in most Western democracies have undergone a fundamental change, starting in the mid-1980s in Anglo-Saxon countries (e.g., United Kingdom, New Zealand) and the Scandinavian countries, and have been followed, finally, by the Continental European Countries with a *Rechtsstaat* tradition (e.g., Germany or Austria) about 10 years later. Hereby, new public management (NPM) served as an umbrella term for diverse reform initiatives to such an extent that the term has come to denote the reform paradigm of the whole era.

Being an umbrella concept, NPM was broad enough to be a reference model for reforms from various ideological backgrounds (e.g., 'Thatcherism' and 'New Labor' in the United Kingdom; the Reagan and the Clinton/Gore administration in the United States) and with quite diverse scopes. In the different countries, reforms connected with NPM ranged from modest modernizing of the administration to fundamentally rethinking the state's role and its administrative architecture (Hood, 1991; Pollitt and Bouckaert, 2011). NPM's principles were mainly underpinned by new institutional economics (e.g., minimization of transaction costs by reconsidering agency-dilemmas and the distribution of property rights) and explicitly directed against Weberian-style bureaucracy. Despite this divergence in scope and content of actual reforms, NPM

entailed some core elements, which, independently from the administrative tradition or political party in power, almost all governments referred to. The creation of (semi-)independent, single-purpose PSOs and the reliance on private-sector management instruments are two of them.

Although (semi-)independent public entities have already existed in pre-NPM times, their quantity as well as their quality has been significantly influenced by NPM-inspired reforms. A common denominator was the assumption that organizational disaggregation, together with the coupling of responsibility for resources and outputs within one single organizational entity, would lead to more efficient and effective service delivery. As a consequence, alongside the traditional centralized and decentralized government bodies (ministries, departments, etc.), public tasks and services were increasingly to be carried out by such (semi-)independent entities. The fact that they were predominantly created ad hoc following a case-by-case approach (Van Thiel et al., 2012) is one of the reasons for the generally low level of formal standardization of PSOs even within single countries.

Moreover, within the traditional administrational units (e.g., governmental departments), measures like the introduction of decentralized lump-sum budgets, contract management with goals and targets, performance measurement, and incentivation, gave rise to the formation of quasiorganizations. Inspired by managerialism – "let the managers manage" (Kettl, 1997: p. 447) – the management of public sector units was widely seen as the main field of professionalization. Business companies served as a role model, which also became apparent in the linguistic usage of terms typical for the business world. Hence, a multiplicity of concepts and instruments was transferred from the private into the public sector (for an overview, see Rainey, 2009), such as the product logic and the idea of a production process of public services, or transfer pricing systems between administrative units. From a steering at arm's length perspective (Hood, 1991), the predominant question of how to "make the managers manage" (Kettl, 1997: p. 454) established a highly performance-oriented view. As a consequence, the decentralization of managerial decision making, management by objectives, and performance-related pay were seen as a proper means to encourage management's commitment with service delivery on the one hand and to foster cost awareness among public managers on the other hand. They also increased management's identification with their single units rather than with the whole government body this unit was part of.

The focus on disaggregation and decentralization led not only to a significant increase in the number of individual organizations, but also to the enlargement of types of organizations – organizational forms – to be found in the public sector. This development was reinforced by a discussion of new roles and changing tasks of the state.

New Types of Activities

The variety of organizational forms is matched by the range of different types of activities PSOs have to perform: Organizational forms and types of activities have evolved separately, but definitely not independently from each other.

Public tasks change over time due to historical, demographic, or technological factors: Some services may become obsolete (such as care for war invalids in Western Europe), some increase or alter (e.g., the need for elderly care), and some new services arise (e.g., e-government services such as online tax declarations). Tasks and activities also change as the underlying discourses and narratives of the state and its public administration shift (Fleischer and Jann, 2011). The movement away from the older welfare state toward the notions of an enabling state, guaranteeing state, or activating state has gone hand in hand with an increase in responsibilities such as regulating and monitoring of liberalized domains and decentralized units that had been created to deliver the devolved tasks. Today, PSOs perform functions as different as service delivery (which is the classical function), regulation (e.g., in the field of infrastructure) and supervision (e.g., of the capital market) of policy fields, or the transfer of various types of subsidies. These different types of activities cover the entire spectrum from acting as a public authority to taking the role of a private market actor.

As a result, the relationship between the state and its PSOs is multifaceted, too: The state – the role of the state may be assumed by central (e.g., federal), regional, or local governments or other legal public bodies such as municipalities, provinces, regions, etc. – acts in a variety of roles, such as owner, funder, regulator, or purchaser of services provided by a PSO. It is equally possible that different units of the state embody different roles in relation to the same PSO and therefore have differing or conflicting interests. State-owned enterprises (SOEs) play a central role not only in Continental Europe, but also in the rapidly developing economies in Asia (e.g., China or Indonesia): They have always been a good example for such internal conflicts of interests, as they are often market-based and for-profit and may compete with private companies. The state as an owner may be interested in returns (or, at least, a minimization of losses), while as a customer, it may be interested in reasonably calculated products of high quality (e.g., postal services). Additionally, the public/electorate (and especially the SOEs' employees) may expect the state to promote fair wages, which alludes to its role as a (direct or indirect) employer. State-owned energy providers are a good and complex example, as their purpose is twofold: On the one hand, they have to secure the state's stake in a field of high strategic importance (organization as instrument); on the other hand, they are expected to deliver returns that go into the overall budget (organization as investment). In cases like rail services, liberalization approaches and, thus, the emergence of competing service providers have led to single entities where infrastructure provider and one core competitor are under the same organizational roof. Problems arising from these models have mostly resulted in the further decomposition into smaller single-purpose units. Market share and power, governance issues (e.g., public corporate governance), regulation under conditions where the regulator owns the biggest or only competitor, or accountability concerns in the absence of a democratic electorate are but a few of the questions that arise from the multifaceted trends related to PSOs.

Heterogeneous Organizational Forms and Blurring Boundaries

PSOs comprise not one prototypical organizational form, but many. While some are very similar to private sector companies and some share many characteristics with NPOs, others like courts, federal banks, or military organizations are fundamentally different. There is no easy or clear answer to questions such as: What defines a PSO? What is the common denominator of this diverse collection of organizations? What features does an organization have to exhibit in order to qualify as PSO apart from the fact that it is somehow located in the public sphere? In fact, questions like these challenge and make blurry or even fluid both the boundaries between the public and the private sector and – from an organizational perspective – the boundaries of a single organization.

As a consequence of this heterogeneity, one can find a considerable number of categories and labels for the different decentralized public entities, such as agencies, nondepartmental public bodies, corporatized units, SOEs, quagos, quangos, etc. Their definitions vary and so do the presumed relationships among them. To give just one example: There is no consensus as to whether 'agency' is an encompassing category that does not denote any particular organizational form and thus, also embraces government administration and departmental units (Australian Public Service Act of 1999 cit. in Wettenhall, 2003), or a specific type describing specific PSOs – those that are "considered suitable for activities that can be shifted out from core government departments, but not very far" (Pollitt et al., 2001: p. 276). While in the first understanding, agency is a synonym for PSO, in the latter agencies are a 'marginal case' of PSOs only, even if states suffered from an 'agency fever' (Pollitt et al., 2001). This multiplicity of forms and labels in the Anglo-Saxon administrative tradition is mirrored in other traditions and languages. It is obvious that this is a considerable challenge for comparative descriptions and research (Verhoest et al., 2012).

What Defines a PSO?

In the literature, several attempts to define and map PSOs have been made (for overviews see Roness, 2003; Thynne, 2003; Wettenhall, 2003). The labeling as 'public sector organizations' points to public sector as opposed to private sector as primary delineating factor. Yet, the decentralization and autonomization trend together with the shift in the predominant conception of the state have led to a situation where public sector activities are increasingly performed in an overlapping area between the three sectors (public, private, and not-for-profit). Pollitt et al. (2001: p. 274) note that the public–private borderline "is increasingly a rather large patchwork zone rather than a line." The adequate blend of sectors in the provision of public services – including contracting out, outsourcing, and public–private partnerships (PPPs) – is even one of the objectives of an enabling state. This complex array of hybrid or intermediate types of organizations – Wettenhall (2003: p. 229) ironically calls it the 'go-quago-quango-nongo spectrum' – has, to a certain extent, dissolved, or at least blurred, the sector boundaries and precludes a straightforward delineation along this feature. This difficulty to clearly differentiate between the private and the public sector is, according to Wettenhall (2003), the 'biggest hurdle' in the way of developing a Linnéan classification of PSOs.

Classifications of PSOs are based on a variety of criteria such as task, ownership structure, legal status, degree of autonomy, financing and budget structure, distribution of financial surpluses, or 'publicness.' Building on the tasks devolved (see also the section above), PSOs are generally categorized as to whether they perform classical functions based on government authority, welfare state activities or economic market-based activities (Bouckaert et al., 2000). For organizations with market-based activities, the term SOE is frequently used (OECD, 2005). Based on the primary type of expenditure, Dunleavy (1989), for example, distinguished between delivery, regulatory, transfer, contract, and control agencies.

Ownership as ordering principle of a classification scheme mostly distinguishes between units that are fully owned by one governmental body, PPPs, and public–public partnerships, i.e., multiple governmental bodies (e.g., in federal systems) together own an organization. However, ownership as a criterion may also turn out to be misleading (e.g., with supranational organizations like the UN), rather vague (as, for example, with trusts or funds) or complex (e.g., when multiple other PSOs are the owners). Drawing on an analogy to private sector group consolidation rather than ownership, control has become useful in defining boundaries (see e.g., the definition of in-house procurement by the EU court, or International Public Sector Accounting Standard 6 on Consolidated and Separate Financial Statements, issued by the International Federation of Accountants). However, the question of control equally requires a case-by-case consideration as it may be based on organizational (e.g., ownership of the majority of shares, contractual agreements to have the right to appoint the majority of board directors), financial (e.g., subsidies that account for the majority of the organization's income), or economic terms (e.g., the state being the only purchaser of the organization's products).

Using the legal status of a unit as characteristic feature differentiates, firstly, entities that do not have a separate legal status (e.g., departmental units) from those that do. Secondly, depending on the legal instruments by which entities have been established, the latter category is further split into public law or private law entities. The practical decision between private or public law is often informed by tax, liability, transfer, or public procurement considerations. Moreover, in the public debate, 'privatization' is often also used for the setting up of an entity according to private law, irrespective of the fact that it remains fully government owned. Thus, the choice of legal status may also be driven by the expected degree of approval by the electorate for privatizations rather than by characteristics of the respective unit. Hence, legal status alone is a weak indicator as to whether the unit should be regarded as a public entity or not.

Also with regard to the level of autonomy, PSOs come in a broad variety, ranging from administrative units given slightly more freedom (e.g., by the implementation of lump-sum budgets or service contracts) to entities with considerable degrees of legal, economic, and managerial autonomy. Although one of the core principles of NPM demanded the separation of policy formulation from execution, some PSOs

were given policy autonomy (in addition to their legal and managerial autonomy), which means that they play a key role not only in the execution of political objectives but also in the know-how based formulation of those goals and targets (Van Thiel et al., 2012). A recent suggestion for a Linnéan System of categorization that builds on different levels of autonomy has been developed, for example, by Van Thiel (2012).

A common distinction between private and nonprofit sector hinges on the distribution of financial surpluses among owners. Although public sector activities are prototypically seen as nonprofit, there are many PSOs that gain profits and are even designed to do so (see especially market-based SOEs). Thus, this distinction is useful for PSOs only to a very limited extent. In some cases, for-profit and nonprofit orientation (and often also public and private law) is mixed, when, for example, PSOs, such as universities, that are generically designed as nonprofit, create for-profit spin-offs (e.g., executive education centers, university-owned consulting companies, university as incubator for innovations, etc.).

Some scholars recommend giving up the categorical distinction in favor of a degree of publicness. Antonsen and Jorgensen (1997: p. 340), for instance, studied publicness as the "degree to which public sector organizations adhere to public sector values" across different functional categories and policy sectors. Another classification of PSOs that tries to account for several of the categories discussed above has been suggested by Pollitt et al. (2001). In their model, different types of PSOs are clustered along two dimensions, ownership (public institutions, public bodies, PPPs, and civil society) and the extent to which the PSO fulfills commercial purposes.

Redefining Organizational Boundaries

Apart from the definition of 'public' in PSOs and the related problem of blurring sector boundaries, the questions of what constitutes an organization and what is the appropriate unit of attention (Roness, 2003) are equally relevant as difficult to answer.

NPM's core idea was to focus on smaller, decentralized single-purpose units; the role model for creating these units was, in many respects, the basic organizational form of the private sector: The corporation. While for management and incentive purposes, this focus on the individual unit may be appropriate, from the perspective of the state and its public sector or even from the perspective of a single policy field, it falls short in many ways. In fact, this imagery of an isolated organization engaging in transactions is no longer regarded as adequate even in the private sector. In the public sector, it is fundamentally at odds with the complexity of the interlocking arrangements and relationships between the state and its various PSOs. Including into the picture arrangements such as outsourcing and contracting out makes the question of organizational boundaries even more challenging with the obvious danger being to miss the forest for the trees.

In the private sector that originally served as the model for NPM-inspired reforms, similar concerns with the focus on single organizational units have been voiced and much effort has recently been devoted to the study of embedded groups of organizations and the network relations between them. In the public sector, an analogous perspective encourages making the whole formation of PSOs and its governance the center of attention. (The analogy of the public organizational landscape and business groups is especially popular among German scholars: see e.g., Reichard (2006) on 'municipal holdings.') The heterogeneity of organizations within the network and the diverse and intertwined power relationships between them certainly provide enough material for in-depth analyses that can generate interesting insights into the working and dynamics of the post-NPM PSO landscapes. Being complex systems, these network formations have characteristic features (Goergen et al., 2010) such as the emergence of typical patterns of behavior, shared norms and values, and a distinct identity. Another common feature of complex systems is entropy, which means that within such systems, strong centrifugal forces are at work. Moreover, their specific formation and the practices, norms, values, and identities they develop are shaped by the cultural, historical, and political context in which they are formed. Thus, although the decisions to construct the individual organizations in whatever form may be ad hoc and nonstandardized, the overall formation is far from being random, but reflects its contextual embeddedness. Consequently, measures to strengthen PSOs' structural and cultural ties within the public organizational landscape are currently at the center of many reform initiatives under the banner of a (new) public governance.

Consequences for Governing

More than two decades of reforms inspired by the principles of NPM have had considerable consequences for the public organizational landscape. Van Thiel et al. (2012: p. 419) mirror very well the disillusionment with these reforms when they state that autonomy alone, even if understood as multidimensional quality combining legal, managerial, financial, and policy aspects, "has proven to be an insufficient condition to increase agency management and performance." In addition to autonomy, means of trust and control, the establishment of a stimulating organizational culture and appropriate governance structures are required. Thus, reforming PSOs in the post-NPM era frequently aims at establishing a shared culture and a general, widely understood, and encompassing governance framework for all organizations in the landscape.

Reform initiatives attend to a range of concerns and introduce related measures that are frequently subsumed under the label of (new) public governance (Osborne, 2010; Pollitt and Bouckaert, 2011) – arguably the new kid on the block of umbrella terms and reform paradigms. A first bundle of concerns addresses the management of networks and multi-actor systems (Rhodes, 1997) as well as legitimacy issues ('good governance': European Commission, 2001). On the one hand, the enabling state and the integration of multiple external actors (such as NPOs and private sector companies) into the processes of public service provision and the creation of hybrid organizational forms demand management systems and steering mechanisms outside the classical hierarchical authority relations. On the other hand, transparency, accountability, or participation are equally demanded from

units operating at arm's length. However, it is much more difficult to secure compliance in fragmented systems.

It has been argued that the main motives for delegated governance and the creation of autonomous organizations lie beyond the increase of effectiveness and efficiency: Instead, depoliticization and impartial execution of public tasks (Van Thiel et al., 2012) was the promise. However, as the authors argue, from a quality of democracy perspective, the increased distance between PSOs and the parliaments and the resulting weakening of democratically legitimized institutions are highly problematic. Concerns not only with increasing expenditure, but with a dilution of political responsibility and accountability, while at the same time political patronage is rising, were based on the insight that PSOs "occupy a niche whereby ministers can remove themselves from direct responsibility for policy implementation" (Flinders and Skelcher, 2012: p. 327). PSOs, initially designed to withstand political interference, show to be likely of falling victim to politicization no less than centralized governmental units, only more hidden.

According to empirical evidence from different countries (Verhoest et al., 2012), the administrations' ability to stay in command of the organizational landscape seems to be rather low, irrespective of different administrative traditions: What is more, forms and instruments of steering, controlling, and directing PSOs turn out to be insufficient to a great extent. As a consequence of the disaggregation, formerly closely tied policy fields seem only loosely coupled and fragmented today. Apart from coordination and coherence difficulties, this leads to a considerable lack of transparency not only for the external public, but also for within the administration itself. Many administrations no longer have a comprehensive overview of their independent bodies. Flinders and Skelcher (2012: p. 329), for example, report that in the United Kingdom, following the new government's attempt to reduce the number of quangos, first attempts to quote correct figures and map the organizational landscape showed that "*nobody* actually possesses a blueprint of the structure of British governance or understands how the various tentacles of the bureaucracy are expected to work together." Undoubtedly, this is no exception.

Although it is certainly true that coordination is "an old administrative doctrine" (Hood, 2005: p. 19), its lack is at the center of reform initiatives attending to the fragmentation and control deficits that have resulted from the unbundling and splitting up of the state into 'single-purpose organizations,' sometimes effected by means of reintegration, in-sourcing and deagencification. Counteracting the focus on measurement and indicators, post-NPM approaches rely on shared norms and values, ethics and the fostering of a distinct public service motivation. The aim is to regain cohesion and coordination ('whole-of-government' or 'joined-up-government' initiatives: among many others see Christensen and Laegreid, 2007; Hood, 2005) across and between levels of government and these highly fragmented and complex bundles of organizations by increasing structural and cultural embeddedness without reestablishing the status quo ante by merely reaggregating them. The challenge is once again to keep a balance of embedded autonomy: This time between the advantages of PSOs' autonomy and the reestablishment of their ties to the public sector and the governmental body they are part of.

Conclusion

NPM-inspired reforms created numerous autonomous units with many different faces and labels. This variety of organizations and organizational forms precludes a straightforward definition of what constitutes a PSO and blurs the boundaries between the public and private sector as well as the boundaries of single organizations. In addition, the complexity of the interlocking arrangements and relationships in this public organizational landscape has resulted in considerable governance problems with serious implications for coordination and policy coherence.

Abstract

Public sphere as a specific sphere, domain, an imagined space of communicatively mediated social life, or a discursively constructed social space between the state and civil (initially bourgeois) society represents the infrastructure for social integration through public discourse. It is taken for granted that no specific social norms (e.g., privacy, ownership) and regulatory rules (e.g., formal membership) limit citizens' access to the public sphere, and no specific knowledge and competences are needed to make them able to participate in it. A public sphere could either be (1) the sphere of publicness, i.e., communication spaces created and maintained by the media, which involve relations of power and dominance ('public space') or (2) the sphere of the public/s consisting of free and equal citizens participating in public reasoning. In either case, the principle of publicness represents the very heart of the concept of the public sphere. In empirical terms, the public sphere is often conceived of as a kind of 'compromise' of these two 'ideal types.' The concept of the public sphere largely refers to the role of the media and public opinion in modern representative democracies; the normative conceptualization of the media comes to the forefront in the idea of public service media.

To analyze the media from the perspective of the public sphere is to focus upon the media's relationship with democracy. The concept of the public sphere has been used to describe the historical development of modern, post-Enlightenment forms of representative democracy and to conceptualize the role of the media and public opinion within them, and has also served as a normative concept with which to pass judgment on the current performance of the media from the perspective of the creation and maintenance of democracy.

Principle of Publicness and the Public Sphere

Central to the concept of the public sphere is the normative principle of publicness. Modern democracy is usually thought of as a product of the enlightenment, when the idea of publicness was raised to a fundamental moral principle; I. Kant (1784) outlined the 'public use of reason' as the fundamental and universal principle of human public agency, and J. Bentham (1791) defined 'publicity' as the foundation of public opinion and people's sovereignty – a safeguard for public confidence in the rulers and an assurance that they would perform their duties. Since the principle of publicness only makes sense in reference to forms of communication beyond transitory interpersonal interaction, the nature of 'being public' – the publicness – in the strict sense could not have existed before the ample expansion of the temporal and spatial horizons of communication brought about by the development of the press. In contemporary (Western) democracies, the idea of publicness primarily refers to the public sphere, where the public use of reason or public discussion of free and equal citizens should result in the formation and expression of public opinion.

In recent years, the public sphere perspective has become dominant in thinking about the media and their political role, by providing, in a return to the central questions of enlightenment political thought, a bridge between Marxist theories of ideology and the liberal 'free press' tradition. It provides a critique of Marxist theories of ideology by revalidating the specificity of the political, by giving due weight to the emancipators potential of liberal bourgeois concepts of free assembly and debate, and by shifting attention from worker to citizen. On the other hand, it provides a critique of an abstract, property-based 'free press' model by stressing both the systemic social barriers to entry and the manipulative distortions to which its discourse is subject. Thus the idea of the public sphere follows Marx's critique of the bourgeois idea that the press might attain its freedom more easily and fully by adopting the laws of free economic operations that rested on the right to private property, which paved the way to the subordination of the press to freedom of ownership as a peril no less dreadful to a genuine freedom of the press than ideological censorship.

The concept of the public sphere was introduced into media analysis with the English translation of J. Habermas's book *Strukturwandel der Öffentlichkeit* (1962, Trans. 1989). In Habermas's original formulation, the term was designed to describe a historical process whereby in the shift from premodern feudal, absolutist rule to forms of modern representative democracy public opinion based upon publicly available information and debate, developed as both a check on, and as a source for the legitimacy of, government. The words 'public sphere' originated in Habermas's *The Structural Transformation of the Public Sphere* 1989, but the idea dates back to Marx's (1843a) early conceptualization of the press as 'the third element' mediating between decision-making political authorities (the 'first element') and civil society (the 'second element'), in which the rulers and the ruled alike can criticize their principles and demands on equal terms, emancipated from their authoritative officiality and private interests as citizens of the state; no longer as individuals, but as intellectual forces, as exponents of reason. Ever since Bentham, the press was considered constitutive of the public and public opinion, but K. Marx was the first to realize that the press is more than just an 'organ of public opinion.' The distinctive feature of the press is, according to Marx (1843b: p. 155), that it can transform a particular interest to a common interest by confronting

the rulers and the ruled; it 'harmoniously combines all the true elements of the popular spirit.' It took more than a hundred years that Marx's idea of 'the third element' has been rediscovered as 'the public sphere' by Habermas.

This return has focused on concepts of the public sphere, civil society, citizenship, and identity. It has in particular pitted those who see the emancipatory project of the enlightenment as unfinished business and wish, in a movement of immanent critique, to hold liberalism to its emancipatory ideals, against a range of communitarians and postmoderns. The latter, in the name of various versions of identity politics, see liberal, rights-based political theories as inherently repressive and their emancipatory and universalizing tendencies as bogus (Gray, 1995).

The public sphere approach has provided, against the background of the turn away from Marxism associated with the collapse of 'actual existing socialism,' an alternative to theories of dominant ideology or hegemony as an explanation for the coincidence, within what used to be called 'bourgeois democracies,' of growing social inequality and political apathy on the one hand with the relative stability and increasingly consensual, nonideological nature of representative party politics on the other. Its emphasis on discursive practices and on communicative action as central to democratic practice and legitimization fitted well with the wider 'linguistic turn' in the human and social sciences. At the same time, its use of the spatial metaphor of sphere, and its stress on the necessary institutional foundations for the realization of those citizen rights to free expression and debate central to democratic theory, addressed the questions arising from both the perceived empirical reality in the mature democracies of an increasingly media-saturated, image-driven, public relations–oriented politics and the task of constructing democracy in both state and civil society in newly democratized countries with little or no historical traditions of democracy to call upon.

It was Marx who first conceptualized that the press not as a simple instrument to create and reflect public opinion but as *a mediator* between the state and civil society. He saw the press as *the site* in which the political state and civil society could meet on equal terms, where *citizens of the state* – "no longer as *individuals*, but as *intellectual forces*, as exponents of reason" – are emancipated from their authoritative officiality and private interests. The free press, Marx argues, can mediate between civil society and the state because it is "*political* without being official, hence not based on bureaucratic premises," and it is "of a *civil* nature without being bound up with private interests and their pressing need" (Marx, 1843a: pp. 189–190). It is based both on reason and emotion; its discourse, both rational and passionate, differs from that of official reports. The distinctive feature of the free press is that it can transform a particular interest to a common interest by confronting the rulers and the ruled, provided that a genuinely public sphere is established in which confrontation between opposing viewpoints is possible, because the difference between rulers and ruled vanishes. It is not only an organ through which the public can express its 'public opinion'; it is also the condition for public opinion and its 'producer' – the public – to come into existence and stay alive.

During the last century, Marx's 'third element' mediating between the state and civil society has developed into a complex 'public sphere' – a kind of communication network and infrastructure enabling the formation of public opinion. The public sphere is normatively understood as a specific sphere, domain, or imagined space of social life existing between, and constituted by, the power structure of the state and civil society. It is the context of public opinion rather than its generator, which always is a public. There is no public without a public sphere, and no public sphere without a public. The existence of the public sphere is vital for a public to become visible through public opinion, and an acting public is a necessary condition for a public sphere to really exist.

The public sphere represents the locus where private citizens engage in the 'public use of reason' (Kant); an infrastructure of social integration through (mass mediated) public discourse, in contrast to political power in the sphere of politics and market mechanisms in the sphere of economy, both of which represent specific forms of social integration through competition. It is activated in the communicative interdependence and rational–critical discourse among citizens potentially affected by transactions in which they do (or did) not participate, in which the legislated laws of the state and the market laws of the economy are (ought to be) suspended.

Only as long as economic and social conditions giving everyone an equal chance to meet the criteria for admission to the public sphere are effectively met, the existence of the public sphere is protected. A clear interest in the (re)production of a genuine public sphere derives from less numerous and less powerful actors, which may be classified into three main categories: (1) citizen demand for media uses and interest in receiving information and opinions; (2) various civil society groups' interest in having access to the media to publish their opinions; (3) a general (ethical) interest of citizens in maintaining the citizen rights and in the media performing their public service functions. However, in practical terms, citizens *qua* citizens do not seem to be among key actors in the public sphere anymore but rather, as in the old Lippmann's theorization, 'deaf spectators in the back row' observing public actors (Lippmann, 1925: p. 13).

The public sphere and the public are inseparably connected to each other – like a system and its component, which must produce results congruent with the defined goal – but the difference between the two is essential in their relation to the organized power of the state. The public sphere is *inseparably connected* with the state, which is one of the actors in the public sphere and, at the same time, its legal guarantor, whereas a public is formed more or less *in opposition* to the organized power of the state.

We may think of the public sphere as a kind of communication framework of the 'body public,' a sphere of channels of opinion circulation binding and protecting its constituent publics. The public sphere is the arena in which civil society informs itself and exchanges ideas and opinions with other social actors representing the two remaining realms, those of the state and the economy. It would be delusive, however, to equate 'the public sphere' with 'the sphere of publics.' Beside public/s as a communicatively acting social category consisting of formally equal citizens appearing and acting in relation to some important and controversial social–political issues, whose participation is constitutive of the public sphere, two additional major classes of actors appear in the public sphere *in front of*

publics: (1) state authorities, political parties, interest groups, politicians, media owners, commercial corporations, business elite, and similar actors as coauthors and addressees of public opinions who use the already constituted public sphere, and (2) media gatekeepers – journalists, editors, and publicists – who are the agenda-setting gatekeepers of public discourse. The former potentially imperil publicness of the public sphere in the measure that they bring manipulative publicity in the public sphere by subsidizing information to frame and set the agenda of public discourse. This 'new publicity' represents a constant danger of confounding public actions of elites with a public sphere.

Mass Media, the Public, and the Public Sphere

The public sphere as the infrastructure for social integration through public discourse is largely based on media operation. Mass media are not only constitutive of the public as an 'imagined communion,' which can only come into existence through the media, but also vitally important for the creation of an institutionalized (infra)structure of the public sphere. Mass media are, as Tönnies (1887: p. 221) suggested for the press, "comparable and, in some respects, superior to the material power which the states possess through their armies, their treasuries, and their bureaucratic civil service." Ideally, they channel the flows of discourses from opinion formation in the networks of the public sphere to the political will-formation in the political system and vice versa.

It is not just any media on which the public sphere can be build up. As 'organs' of (opinion of) the public, the media have to perform specific normative functions along the principles of publicness set forth already by Kant and Bentham. Personal freedom of public use of reason and the right of the public to control political authorities are hardly compatible with the media owned by private capital or the state, which adopt media-centered strategies to maximize commercial profit or political power. The initially beneficial consequences of incorporated media as private businesses faded away with the industrialization, commercialization, and monopolization of the press and other media. Marx (1842: p. 68) admitted that "it is no transgression, when a German perceives the unknown goddess of freedom of the press as one of the goddesses he already knows, [as] freedom of entrepreneurship or freedom of ownership." Even if 'enacted' as freedom of property rather than personal freedom to communicate, freedom of the press had temporarily beneficial consequences for the autonomy of civil society and the public sphere in the early phase of liberal capitalism. In the long run, however, the subsumption of freedom of the press in the 'general freedom' of entrepreneurship as the fundamental principle is a fatal degradation of the press.

The subordination of newspapers to powerful commercial and party-political interests in the late nineteenth century brought about the idea of public service newspapers even before the emergence of radio. Many press reformers pleaded for 'security valves in public life' based on charitable funds, which ought to limit the dependence of newspapers on owners, political parties, and advertisers, to prevent sensationalism, and empower people's voices to find their expression in the newspaper to serve the common good together with journalists and editors (Tönnies, 1922). Similarly, C. Bücher (1926: p. 53) saw the main task of the press in enabling the circulation of results of intellectual work in politics, science, arts, and technics, which is why it should be made available to citizens for free. The idea of public service clearly failed in the field of the press even though newspapers were constitutive of the bourgeois public sphere emerging in the seventeenth century. The reason seems to be rather simple. The idea of the 'public service press' emerged rather late; it was actually behind time since newspapers already became powerful economic players, and no social force or political actor existed influential enough to limit their power at that time. Newspapers' owners would ideologically legitimize the rejection of such ideas by denoting them as attacks on 'freedom of the press.'

Essentially, we can find those ideas condensed in subsequent definitions of *public service (radio) broadcasting*. This model prevailed in Britain until the 1960s and influenced the organization of broadcasting in many other countries, particularly (but not exclusively) in Europe. Later on, it was complemented by private commercial broadcasters in the so-called 'dual broadcasting systems.' A rather clear echo of early public service ideas one can come across in a modernized version of the definition of public service broadcasting adopted by UNESCO, although it fails to recognize the importance of the 'direct expression of people's voices' in the media: "Public Service Broadcasting (PSB) is broadcasting made for the public and financed and controlled by the public. It is neither commercial nor state-owned. It is free from political interference and pressure from commercial forces. Through PSB, citizens are informed, educated, and also entertained. When guaranteed with pluralism, programming diversity, editorial independence, appropriate funding, accountability, and transparency, public service broadcasting can serve as a cornerstone of democracy."

In an economic perspective, the idea of public service is often associated primarily with the natural scarcity of goods (e.g., the scarcity of radio frequencies in the predigital era) or complexity of services exceeding individual investment capacities (e.g., military defense), which would justify a strict state control or even monopoly. Since there is no such scarcity in the digital era any more, it should follow – according to this view – that there is also no need for public service broadcasting any more; thus consumer preferences and demands could 'freely' determine the program supply on the media market.

The scarcity argument against media regulation is questioned for three main reasons. First, a true competition of the mass media is not likely to materialize since the entry costs to the media market are prohibitively high. Media concentration in the hands of a small number of corporations taking place both nationally and globally may severely restrict the possibility of nonmainstream 'consumers' to influence the program supply.

Second, legal regulation has been introduced by modern states in virtually all areas of production of goods and services – from food and pharmaceutical industry to aircraft industry and transportation – to protect consumers and society at large.

Third, the mere plurality of even perfectly competitive content providers would not guarantee diversity of the supply. Extremely competitive media markets may tend toward

homogeneity even more likely than monopolistic or oligopolistic media systems because media markets tend to reflect only mainstream preferences and demands of audiences.

In a broader perspective, the concept of public service is rooted in historical processes of human emancipation and thus closely linked with the virtues of human freedom and equality. It implies a broad societal consensus that certain services should be made available to all members of society on a non-profitable basis, regardless of the differences between them in terms of income, social status, cultural habitus, or ethnic affiliation. Such a consensus is based on the recognition that those services are fundamental to human life and thus have to be universally guaranteed and provided. The universal provision of such services associated with fundamental human rights and liberties is an ethical imperative. Even if some public services are not publicly financed (e.g., education provided by private schools), they are subject to a more strict legal regulation and public control than pure commercial sectors.

Mass media can be considered a case in point; since any kind of publication through the media has a public nature and public significance, it calls for specific legal regulation to implement the principle of publicness and privacy protection, which are both related to the personal right, and human generic ability and need, to communicate. It is often taken for granted that freedom of thought and opinion does not legitimately invite public regulation because it is individual rather than intrinsically collective exercise of freedom. Such a belief is essentially delusive as the personal right to use one's reason *in public* can only be realized in community with others.

The normative view that mass media have specific responsibility to serve (civil) society in which they operate is for some an axiom that hardly needs explanation since the media are an integral part of modern social system with significant political and cultural functions for individuals and society as a whole. The opposite view holds that a true freedom of expression implies not only an absence of any outside interference (market forces are considered 'insiders' in the process), but also a lack of obligation to meet any outside claims, especially those backed by force or authority.

Early radical critiques of the commercialization and politicization of the press in the late nineteenth century considered socialization of the press a fundamental condition of its liberation from the subordination to the state, political parties and, particularly, commodity production. They related the ideas of press reforms that would establish the press as public service to the 'extension' of personal freedom of expression and democratization of society, which would make the press a matter of genuine common concern and decision making. But the early critics also realized that reforms could not be limited to the questions of political and economic (in)dependence of the press because the genuine socialization of communication activity stands and falls together with the general democratization of economic and political relations, which substantially affect all forms of human communication.

The general idea of public service points out the principle of equal access to consumption of services or goods in question without any reference to the principle of *publicness*, whereas the public service model of the media is not defensible as just *any* kind of service to the public. This is where the specific idea of public service in the sphere of (mass) communication substantially diverges from the idea of public service in general. Since the media may be considered the guardians of the principle of publicness in modern societies, this principle is central to the concept of public service media and its unique feature.

The specificity of public service media can be defined in reference to two related issues: (1) the nature of contents produced and published (broadcast) by the media and (2) the constitution of the public, which ought to use public service media as its 'organs.' In normative terms, public service media as organs of the public (or publics) provide a service *of* the public, *by* the public, and *for* the public. It is a service *of* the public because (if) it is financed by the public and controlled by it. A service *by* the public – not only financed and controlled, but also produced by it. A service intended *for* the public – but also for the government and other powers acting in the public sphere.

Table 1 presents schematically the main differences between paternal, commercial, and public service media systems in terms of their obligations to those with legitimate power to influence and/or control the media. The media owe responsibility to seven major groups of legitimate actors: (1) their owners, private or state/governmental, (2) clients from the world of the corporate capital, such as advertisers, (3) politicians, (4) interest

groups, (5) professional organizations of occupational groups employed in the media, e.g., associations of journalists, (6) media audiences, and (7) civil society. The relationships between the media and seven groups of actors differ in terms of the source of legitimacy of responsibility claims by these actors and the ways the claims are regulated but also depend on the amount of power specific actors have. The dominant actors influence the media not only to maximize profits or power in the political sphere but also to maintain influence over and against other actors in the public sphere.

For example, privately owned commercial media are more likely to respect responsibility claims by their owners, major commercial partners, and audiences. If the media are kept under state (governmental) surveillance, they are not able to expose political elites to public surveillance. Inasmuch as political and corporate economic elites overlap, corporate control of the media may also disable them from performing their watchdog function.

In contrast, public service media are expected to have stronger professional (ethical) commitments and, in particular, obligations to civil society. As a result, public service media may enjoy greater autonomy from the political and economic power actors due to more dispersed responsibilities whereas in commercial media, profit-seeking interests may limit substantially authentic media autonomy. Moreover, participation of civil society associations in operation of (public) media not only enables civil society to act more effectively, but also contributes to democratization of society by and large.

Without an effective power of civil society to influence the media in terms of its values, interests, and preferences, the idea of public service media would be deprived of its constitutive principles of publicness and personal communication freedom. The power of other actors influencing public service media would excessively increase, and the difference between private and public service media would eventually disappear – to the detriment of civil society and democratic social order.

Public service media may be seen as representing a shrinking minority voice in today's global media landscape. Nevertheless, in the period of newspaper and journalism crisis, the idea of public service becomes redemptive not only in terms of (normative) theory, but also in terms of practical solutions. The recent global newspaper crisis indicates that the production and consumption of media contents could not be left to the market without serious 'collateral' damages, as Bücher and Tönnies have argued long ago. Following the model of public service broadcasting or public university by providing economic stability to the press and promoting journalistic autonomy necessary to serve the public good is believed to be an important step to protect the opinion-forming press, which is fundamental to the existence of the public sphere. It is primarily the responsibility of public service media to be instrumental in the formation of an inclusive public sphere because they are best suited – as indicated in Table 1 – to make it accessible to all citizens regardless of their social status.

Critical Issues

Research and debate around the public sphere and the media now focus on five issues. The first is the question of democratic achievements and failures of the Internet in democratizing public communication. The popularity of the public sphere concept was given a strong impetus by digital(ization of) media in the 1990s. The ubiquity of the Internet in social relations also brought about new puzzles about the public sphere concept. The Internet is much more than just new information and communication technology; its development embodies, reproduces, and sustains forms of social organization spread through the entire social structure. Although the public sphere is not formed around a single medium but is built up as an infrastructure with a variety of communication media, institutional and cultural frameworks as its pillars for organizing public deliberation, the rise of the Internet enabled several civil society actors, particularly in the realm of 'alternative politics' (e.g., women, religious actors, environmentalists, labor, peace activists, gay and lesbian activists, humanitarians) to act on a larger scale and to become more visible both nationally and transnationally. How effective their actions are because of that in terms of impact on public opinion and decision makers is another question. In some cases, the Internet may have contributed to the transgression of fragmented cultural and political interests, but it also may have deepened the fragmentation. It is less efficacious in generating public opinion than the 'old' media. The question is whether the online media and networks across the world can lead toward a 'transnational public sphere' (and transnational publics) or rather toward the fragmentation of mass audiences – who are (were) large, dispersed, and predominantly national, but nevertheless focused on political issues defined by the media – into many dissociated 'issue publics.'

The second question is the institutional question of the relationship between the political public sphere and the nation-state. Both the actual institutional development of the modern mass media, the public sphere, and representative democracy, and thinking about them, have taken place within a nation-state framework. It is argued that current globalizing trends, both within society at large and within the media, are undermining this nation-state foundation of both democratic politics and its associated political public sphere. The question is then whether this is a process of cultural and discursive emancipation and the beginnings of the construction of transnational public spheres or, on the contrary, is a further tightening of the screw of refeudalization, which places the key centers of power outside the structures of democratic accountability and rational critical debate.

On the one hand, the trends toward globalization within the media can be exaggerated. For reasons of audience taste and interest, most media output, and the organizations that provide it, remain obstinately linked to local, often national, markets, cultures, languages, and political structures. There are few examples of successful transnational newspapers or broadcasting news services. Even in the field of entertainment their spread is limited. This is itself, as the example of the European Union shows, a major barrier to the construction of a transnational public sphere. On the other hand, it can be argued that current developments on the World Wide Web, particularly its use for mobilization, debate, and advocacy by NGOs, are a welcome start in the construction of a global

public sphere. What certainly is the case is that the development of global media has begun to create a situation where nation-states, both within their own borders and in their inter-state relations, are having increasingly to take account of global public opinion (e.g., the cases of Tiananmen Square protests of 1989, the Balkan wars in 1990s, the 2003 invasion and subsequent occupation of Iraq, the Arab spring in 2011).

Third is the discursive question of how we can both analyze and normatively judge from the perspective of democracy the wide range of rhetorical forms used and identities appealed to within the range of modern media and the changing nature of publicness. The type of reflexive publicness developed with newspapers and reading publics cannot be compared with publicness as visibility that emerged with television. Television brought about a new type (or at least dimension) of publicness – direct visibility – and consequently changed the nature of the public and public discourse. The availability of broadcasting to almost every citizen (at least in the most developed countries of the time) changed the character of publicness not only because of the (re)introduction of the visual dimension, but also because it widened the notion of 'public interest' by the inclusion of ordinary people into the public domain. This process continues with the development of many-to-many mass communication enabled by the Internet. Here the debate around the public sphere reprises an older debate about mass culture.

The question at issue is whether current developments in media forms, genres, and their associated audiences/publics is a liberatory process of demassification and cultural pluralism on a global scale or, on the contrary, whether it is a process of 'dumbing down,' which in its appeals to irrationality and social fragmentation, undermines the rational/universalistic norms upon which citizenship, and thus democracy, rest. In the press, attention is focused on tabloidization, i.e., the stress on the scandalous and the sensational and the coverage of politics according to the norms of show business; in broadcasting on the shift in the balance of the programing mix in favor of entertainment at the expense of news, current affairs, and political coverage and debate, a shift associated, at least in Europe, with the retreat of public service broadcasting in the face of increasingly intense commercial competition for audiences and revenues.

Analysis and debate have focused in particular on the spread of audience participation shows of the Jerry Springer type, of 'docu-soaps' and of a general sound-bite coverage of politics and public issues. In this debate, there are no easy answers. First, empirically the trends are by no means as clear cut as many critics claim. It is as easy to argue for a rise in standards. Second, it is all too easy to fall into familiar elitist or populist stances, neither of which take due account of the complexity, both actual and historical, of the construction of the identity of citizens or of the rhetorical problems of communicating with the generality of such citizens. There is also often a danger of stretching beyond breaking point the proper and necessary boundaries of politics and the public sphere.

Fourth, there is the question of the role of the mediators. Public sphere theory finds it difficult to break free from a participatory model of direct democracy. Representation always introduces a potentially distorting element into the communication process between the private citizen and political whole. The public sphere is conceived of as an infrastructure for private citizens to publicly express their opinions and participate in public debates to which all have equal access. The ideal model is the Athenian agora. The scale, social complexity, and specialization of the modern world make such a model unrealistic. It has clearly never fitted the actual forms and practices of the (public service) media. It therefore leads to unrealistic demands being made upon them and to an excessively dismissive critique when these demands are not met. It has, in particular, led to exaggerated claims being made for the democratic potential of the Internet on the grounds precisely that cyberspace is a new agora without mediators or mediation. The challenge, therefore, is to think of a legitimate role for mediators and gatekeepers within the public sphere – for journalists, TV producers, bulletin board moderators, etc. – which is neither one of pure transparent 'objective' mediation nor one of the mere pursuit of instrumental professional or economic self-interest. This, in its turn, links to the wider question of the social and political role of intellectuals and experts within modern democratic polities.

The fifth question addresses the controversial relationship between publicness (free public expression and access) and secrecy (censorship) as its opposite, which became a burning issue with recent WikiLeaks' and E. Snowden's actions toward disclosure of 'classified, censored, or otherwise opaque documents' to the public record, by following the Benthamite and Kantian belief that "the public scrutiny of otherwise unaccountable and secretive institutions forces them to consider the ethical implications of their actions" (https://wikileaks.org/). Yet the 'ideology of publicness' is charged by others not to be able to acknowledge that, because of the persistent presence of legitimate secrecy, the public in the strict sense cannot exist. Rule- and decision-making bodies often try to avoid publicness, which they believe would slow down the process or make it less effective because of the inclusion of all potentially affected in public debate. Secrecy is believed to be well (legally) grounded for certain activities of (particularly global) governance such as small-group decision making, political negotiations, diplomacy, gathering of commercially, military, or other sensitive information. Others would argue that this is the conflation or even the swap of privacy with secrecy (secreted private interests, which I may not declare publicly), which for Kant was an exemplary instance (e.g., secret treaties) of an unjust maxim representing a threat to everyone and to universal peace. Although secrecy is essentially the negation of publicness, it is also codeterminative of publicness: by defining its limits, secrecy also constitutes publicness, whereas public reports by exposing certain issues to public attention at the same time hide from it issues considered unworthy of publication (Gouldner, 1976). Consequently, it is exactly actions directed against the conditions (re) producing secrecy, which can bring us ever closer to the counterfactual ideal of 'the public' rather than prove that it cannot exist.

Abstract

This article examines the emergence of a public sphere in eighteenth-century Europe. Its first part is devoted to the successive or competing historical and historiographical definitions of what the 'public' considered either as located within the new forms of intellectual and polite sociability (salons, clubs, masonic lodges), or as opposed to the private use of the reason and made possible by the circulation of written and printed culture, or as conceived in contrast with the popular opinions. The works by Jürgen Habermas, Immanuel Kant, and the French philosophers of the Enlightenment illustrates these different perspectives. The second part of the article identifies the metaphors used for designating public opinion in the eighteenth century. It is conceived either as a unanimous voice to be heard or as a tribunal of which the judgments are endowed with a supreme authority. Defined as a conceptual entity, public opinion was incarnated by different printed genres the memories published by the lawyers, which transformed particular causes into political or social issues, or the pamphlet and libels, which condemned in the name of the opinion the despotism and depravation of the monarchy. The article finally stresses the limits implied by such a conception of the public sphere: on the one hand, the popular milieux are excluded from the public use of the reason reserved to literate and learned individuals, and, on the other hand, the women are deprived since the 1770s of the role they played before in the absolutist or enlightened salon society.

Any reflection trying to understand how the notion of public sphere was constructed in the eighteenth century is necessarily referred to the classical book published by Jürgen Habermas in 1962 (Habermas, 1962). According to Habermas, the 'political public sphere' was construed in the eighteenth century (in some places sooner, in others later) as a space for discussion and exchange removed from the control of the state. The new 'public sphere in the political realm,' founded on the exercise of public criticism was thus opposed to the 'sphere of public authority' identified with the exercise of state power. For Habermas, this new intellectual and political 'space' was distinct from the court, which belonged within the domain of state power, and from the common opinions of the people who had no access to enlightened critical debates. This is why it is possible for him to qualify it as 'bourgeois.'

Definitions of the Public

There were different ways of conceiving the construction of the new political public sphere of the eighteenth century. Was it issued from the literary controversies of the seventeenth century and rendered possible by the diffusion of new forms of intellectual sociability? Or was it the extension of the modalities of print communication proper to the Republic of Letters to a greater number of individuals, which made possible the transformation of dispersed private persons into a unified public community?

Habermas's Political Public Sphere

For Habermas such a 'public' supposed, on the one hand, that the various participants were not acting as agents or subjects of the ruler and, on the other hand, that they were considered as equal. The political public sphere thus ignored both the obedience required by the exercise of state power and the distinctions of 'orders' and 'estates' imposed by the traditional social hierarchies.

No limit could subject the critical exercise of reason, and no domain was to be forbidden to it. Overcoming the division instituted by the cartesian methodical doubt between opinions that could legitimately be submitted to examination and obligatory credences and obediences, the members of the new public sphere considered that no domain of thought, including the political and religious ones, was to be removed from critical and reasonable judgment.

This judgment was exercised within the different forms of sociability, which had been previously erected as a tribunal of aesthetic criticism: the salons, the cafés, and the clubs. In the seventeenth century, this new public challenged the traditional monopoly of the court, the official academies, or the connoisseurs in such matters. It was enlarged during the eighteenth century, thanks to the multiplication and diffusion of the periodicals, and the success of new forms of association: the book clubs, the reading societies, the masonic lodges. But it supposed also the exclusion of all those who lacked the competence which made possible the participation into a critical community welcoming only the persons who had sufficient wealth and culture.

Kant's Public Use of Reason

Habermas's perspective was based on one of the most famous text of the eighteenth century, Kant's *What Is Enlightenment?* published as an article in the periodical *Berlinische Monatsschrift* in 1784. But it also distorted it. In his text Kant proposed a new way of conceptualizing the relation of the public to the private. He equated the public exercise of reason with judgment produced and communicated by private individuals acting 'as scholars before the reading public' and he defined the public as the sphere of the universal in opposition to the private considered as the domain of particular and domestic interests (which may even be those of an army, a church, or a state).

He inverted, thus, the accepted meanings of the two terms by associating the private use of reason with the exercise of an office

or with the duties toward the state and by locating the public use of reason within a community without limitations or boundaries. If the private use of reason can be restrained legitimately in the name of public ends without prejudice to the progress of enlightenment, the liberty of the public use of the reason was absolute and has to be respected by the prince himself.

In this same text, Kant shifted the way in which the legitimate limits put on critical judgment should be conceived. Such limits were no longer defined by domains forbidden to methodical doubt; they laid in the position of the subject who exercises his reason. He could be constrained legitimately when he was executing the duties of his charge or of his status, but he was necessarily free when he acted as a member of the 'society of world citizens.'

That universal society was unified by the circulation of written works that authorized the communication and discussion of thoughts without the necessity of physical presence of the different interlocutors. Kant systematically associated the public use of reason with the production or reading of written matter by private individuals. The public was not construed on the basis of new forms of intellectual sociability, such as clubs, cafés, literary societies, or lodges, because those associations were modalities of particular, circumscribed, and domestic entities. For him, only written communication was admissible as a figure for the universal.

Kant's conception of the public use of reason was drawn for the notion of the Republic of Letters as it was constructed through correspondence and the circulation of manuscript or printed texts from the late seventeenth century onwards (see Goldgar, 1995). Founded on the free engagement of its members, on equality among its interlocutors, and on reciprocity and disinterestedness, the Republic of Letters which united the learned and the scholars provided a model and a support for thinking of the new public sphere. At the same time, it showed the distance separating the universality of the 'society of world citizens' and the restricted social composition of the 'reading public.' In Kant's time, this reading public was not the whole of society by any means, and those capable of writing were even less numerous. It is only when everyone will be able to exercise critically one's reason that humanity will experience 'an enlightened age.'

The French Philosophers: Public Opinion versus Popular Opinions

Kant held the distinction between the public and the people to be temporary, transitory, and characteristic of a century which was an 'age of enlightenment' but not yet an 'enlightened age.' But for many thinkers of the eighteenth century, particularly within the framework of the French Enlightenment, the two notions constituted an irreconcilable dichotomy (see Ozouf, 1989: pp. 21–35). Public opinion was defined precisely in contrast to the opinions of the multitude. Public opinion, set up as a sovereign authority and a final arbiter, was necessarily stable, unified, and founded on reason. The universality of its judgments and the constraining self-evidence of its decrees derived from that unvarying and dispassionate constancy. On the other hand, popular opinions were multiple, versatile, and inhabited by prejudice and passion. Such a qualification reveals a strong persistence of older representations of the people considered as subject to extremes, inconstant, and foolish.

When the concept of public opinion did emerge in France around 1750 as the superior authority to which all particular opinions must bow, the distinction between the public and the popular became essential. A new political culture thus took shape, which transferred the seat of authority from the will of the king alone, who decided without appeal and in secret, to the judgment of an abstract entity embodied in no institution, which debated publicly and was more sovereign than the sovereign who was obliged to seek to win its approval and support.

This gave acuity and urgency to a fundamental question: how could the people, eliminated from the exercise of critical judgment by their lack of competence, be 'represented' in the new political space? A first answer to this question assigned this function to one or another of the theories of political representation confronted after the mideighteenth century. Following Keith Baker, three of the theories were fundamental: the absolutist theory, which made the person of the king the only possible representative of a kingdom divided into orders, estates, and bodies; the judiciary theory which instituted the Parliaments as interpreters of the consent or remonstrances of the nation; and the administrative theory, which attributed the rational representation of social interests to municipal or provincial assemblies founded not on privilege but on property (see Baker, 1990).

An alternative model of representation that removed the notion institutional setting – monarchical, parliamentary, or administrative – was offered by the category of public opinion. Substituting the self-evidence of unanimity to the uncertainties of particular and popular opinions, detached from any form of exercise of governmental and state authority, the concept delegated the representation of the whole nation to those who were able to express its reasonable decrees: the men of letters.

Public Opinion: Voice or Tribunal?

Although everyone recognized the existence of public opinion and postulated its unity, there was no unanimous consent on two issues: first, who were its true spokesmen and, second, how was one to evaluate the self-evidence of its judgments? In eighteenth-century France, the answers to such questions were expressed through the metaphors used to designate this new entity: public opinion as a voice to be heard; public opinion as a tribunal, which had to be persuaded.

From Theater to Tribunal

In 1775, in his *discours de réception* before the *Académie francçaise*, Malesherbes forcefully expresses the idea, by then commonly accepted, that public opinion was to be considered a court of justice more imperious than any other. It is a tribunal 'independent of all powers and that all powers respect,' composed by the men of letters who are 'amid the public dispersed, what the orators of Rome and Athens were in the middle of the public assembled.'

There are several arguments contained in this comparison. First, it invested the new 'judges' with an authority that ordinary judges did not have. Their competence knew no bounds and their jurisdiction no limits; their freedom of judgment was

guaranteed because they were in no way dependent upon the power of the ruler; their decrees had the force of self-evident propositions. With such a definition of public opinion, the men of letters were invested with the judiciary legitimacy of all traditional powers and with veritable public office.

Reference to this dispersed judiciary function had another meaning, however. It aimed at establishing a connection between the universality of judgments and the dispersal of persons, and at constructing a uniform opinion, which, unlike that of the ancients, had no physical location in which it could construe and experience its unity. As for Kant later, it was the circulation of written matter and particularly the printed one, which made it possible to envisage the constitution of a unified public in a nation in which people were necessarily separated from each other and formed their ideas individually. By associating the public nature of the written word, vastly increased by the invention of the printing press, with the supreme authority of the judgments pronounced in the new political sphere, Malesherbes (as many others) converted the plurality of reflections and criticisms that emerged from solitary reading into a collective and anonymous conceptual entity.

From the seventeenth century to the eighteenth century there had been a radical shift in the manner of conceiving the public. In the age of baroque politics the traits that defined the public were the same as those which characterized theatrical audiences: heterogeneous, hierarchized, and formed into a public only by the spectacle in which the most powerful effects were produced by hidden machines and secret maneuvers.

When the concept of public opinion did emerge, it effected a dual rupture. It opposed the art of dissimulation and secrecy by appealing to transparency. Before the tribunal of opinion all causes were to be argued without duplicity. But all citizens were not (or not yet) adept at joining together to form enlightened opinion. If the audience which mingled in the theaters potentially was composed of men and women from all social levels, the public which served as the tribunal to judge literary merits, religious matters, or political issues was more selected and homogeneous. When opinion was thought of more as actor than as acted upon, it became public, and by that token it excluded many people who lacked the competence to establish the decrees, which it proclaimed.

From Audience to Public

Constituting the public as an entity the decrees of which had more force than those of the established authorities supposed several operations. They can be exemplified by the memoirs published in great number by both French lawyers and litigants from 1770 onward. They took the judicial comparison literally and exposed before opinion affairs, which were examined by a court of justice. The cases subjected to the secret procedures of justice were thus transformed into public debates, shifting the place in which judgment had to be pronounced (see Maza, 1993).

The most fundamental strategy required by such an operation consisted in endowing particular cause with general and exemplary value. The debt that a court noble refused to pay to his bourgeois creditors became an ideal occasion for denouncing unjust privilege, just as the arbitrary imprisonment of a young gentleman was an opportunity to criticize the *lettre de cachet*. To achieve such goals supposed, first, that the secrecy of judicial procedure had to be broken by the circulation of printed memoirs on the largest possible scale, and, second, that a dramatic style or a first-person narrative had to replace the customary legal prose. Universalizing the particular, making public what had been secret, and 'fictionalizing' discourse were the techniques that lawyers used to appeal to opinion and, in doing so, to proclaim themselves the authorized and legitimate interpreters of that opinion.

The traditional, discrete, and exclusive relationship that bound individuals to the king, the guarantor and guardian of domestic secrets, gave way to a totally different situation in the public exposition of private conflicts. From that point of view, judicial memoirs are the exact inverse of the *lettres de cachet* accorded by the sovereign in response to requests from families interested in concealing familial disorders, which sullied their honor. The memoirs displayed what the *lettres* concealed; they expected from the judgment of opinion what the *lettres* hoped to gain from the omnipotence of the monarch; they converted into public issues the scandals that the *lettres* were charged with burying.

It is in this sense that the new public space was built on conflicts proper to the private sphere, assigning political significance to simple familial or conjugal strife. In a parallel manner, the clandestine pamphlets stigmatized the aristocracy, the courtiers, the queen, and finally the king by revealing their corrupt mores. People became accustomed to seeing individual affairs transformed into general causes. This procedure was not restricted to pamphlet literature but also lay behind the lawsuits instituted by rural communities against theirs landlords or by journeymen workers against their masters. It was the process of 'privatization' in which individuals conquered autonomy and freedom removed from state authority, which permitted the very existence of a new public sphere.

Even if, or because, it was defined as a conceptual entity, and not in sociological terms, the notion of public opinion which invaded the discourse of all segments of society – political, administrative, judicial – in the second half of the eighteenth century operated as a powerful instrument for social division and legitimization. The mobilization of the category founded the authority of all who, by affirming that they recognized its decrees alone, set themselves up as mandated to pronounce its judgments. Universal in its philosophical essence, the unified, enlightened, and sovereign public was far from universal in its social composition. The public sphere, emancipated from the domain in which the ruler held sway, thus had nothing in common with the shifting opinions and blind emotions of the multitude. Between the people and the public there was a fundamental difference.

Prohibited Books, Subversive Words

According to Darnton, this new public was detached from the traditional authorities by a wider and wider dissemination of philosophical ideas. In this process the role played by the great classics of the Enlightenment was perhaps less important than the texts that the eighteenth-century book trade called 'philosophical books': critical pamphlets, scandal mongering

chronicles, anticlerical satires, pornographic works. The circulation of this clandestine and seditious literature, which depicted the despotic corruption of the monarchy or the depraved mores of the court, engendered a change in thought and in collective representations, henceforth detached the subjects from their old loyalties: "Sedition was hatching. It was instilled in people's minds […] We know for certain that it was communicated by a formidable instrument: the book" (see Darnton, 1991, 1995).

But other historians like Farge have challenged this interpretation that sees the increase in seditious writings in the last two or three decades of the *ancien régime* as the matrix of a desacralization of the monarchy. She affirms: "Popular opinion did not emerge from the cumulative reading of pamphlets and placards; it was not unilinear and did not base arguments on the sum of what is read" (see Farge, 1994: p. 35).

Statements of disapproval or hatred of the sovereign, attacks on his acts, and expressions of a desire to kill him did not arise from the flourishing clandestine literature. Nor did they start with Damiens's attempt to assassinate Louis XV, which, rather than unleashing a proliferation of regicide discourse, persuaded the authorities of the reality of Jansenist and Jesuit plots and set them in pursuit of such literature. For Farge, "the failed murder of Louis XV had a ready-made public opinion; it tells us more about the monarchy's reactions than about any new and original turn of popular thought" (p. 174).

The symbolic and affective disinvestment, which transformed relations with authority when it was deprived of all transcendence was manifested but not caused by the wide diffusion of 'philosophical books.' The erosion of founding myths of the monarchy, the desacralization of royal symbols, and the distancing of the person of the king formed a body of representations which was 'already there,' 'ready made' when the public sphere arose conceptually and sociologically.

Women and the Public Sphere

What was the role played by women in this new public sphere? Joan Landes' thesis opposes radically the "symbolic politics of the emerging bourgeois public sphere (which) was framed from the outset by masculinist interests and assumptions" with the forms of sociability dominated by women in the *ancien régime*, for example, the salon society conceived as "an alternative sphere of cultural production inside absolutism" (Landes, 1988: p. 40). This is the reason why the exclusion of women from political rights during the French Revolution is inscribed by Landes within the logics of the enlightened condemnation of the role that women played within the *absolutist* public sphere: "the structures of modern republican politics can be construed as part of an elaborate defense against women's power and public presence" (p. 203).

Against such a perspective Goodman argues that women played a central role both in the collective project of the Enlightenment and in the construction of a new political and critical public space. For her, "the French Enlightenment was grounded in a female-centered mixed-gender sociability that gendered French culture, the Enlightenment, and civilization itself as feminine" (Goodman, 1994: p. 6). In this perspective the salon society did not belong to the old regime absolutist public sphere but had a fundamental role in shaping a 'discursive space' opened to public and political criticism. Between 1750 and 1775 women were essential in the government of such society because they kept within the limits of civility and politeness the tensions, which necessarily arose from the free confrontations of opinions and the competitions for intellectual leadership: "Enlightenment salons were places where male egos were brought into harmony through the agency of female selflessness" (p. 104).

According to Goodman (1994: p. 280), it is during the 1770s that women began to be excluded from the new public sphere. On the one hand, the harmony of Republic of Letters was then destroyed by a series of a ferocious discords starting with controversies about Physiocracy. On the other hand, new forms of association (among them, literary societies called *lycées* or *musées* and masonic lodges) either excluded women or gave them a subordinate position. The return to 'masculine self-governance' prepared women's expulsion from the revolutionary political space: "When the literary public sphere was transformed into the political public sphere in 1789, it had already become masculine; the 'democratic' republic of 1792 would reflect the limitations and exclusions of the Republic of Letters of the 1780s."

It is possible to discuss such an interpretation. The Freemasonry did not ignore women's presence and gave them an important role in the 'lodges of adoption.' In these lodges many women were involved in the new values coined by the late Enlightenment: the philanthropic activities, the interest for political issues, the friendship between men and women (Burke and Jacob, 1996: pp. 513–49). Besides that, it is clear that even between 1750 and 1775, the salon society was always very minoritary and limited to a restricted number of participants. They cannot be considered as the center of the Republic of Letters.

The collective construction of the new public sphere cannot be reduced either to a unique process or to a sole place. It arose from the intertwining between conceptual novelties and social practices, the alliance between speech and print, and the common (but dissimilar) participation of men and women.

Abstract

The development of institutions and practices of open communication concerning affairs of common interest is basic to democracy. This is analyzed as involving transformations of public space from the Athenian agora to the metaphorical space of electronic communications. These spaces provide for communication among strangers as well as those joined by bonds of community; they are arenas for the expression of individual and collective identities as well as for the making of collective decisions. Analytic attention focuses largely on questions of access to publics, which is often restricted on bases such as gender, ethnicity, or citizenship. It focuses also on institutional supports for public communication, on the relationship between rational-critical communication and other forms of action in public, and on the differentiation of public communication into multiple partial publics.

The closely related concepts of public sphere and public space are rooted in ancient Greek distinctions of public and private and developed in early modern Europe through changing ideas of citizenship, civil society, and republican virtue (*see* Civil Society and the Public Sphere: History of the Concept). They refer first and foremost to settings for political discussion among citizens about the order of their lives together, and secondarily to a much wider range of public culture including art, literature, and popular discourse on a host of subjects.

Publicness as a Modern Concern

New ideas about public discourse were complemented by development of new communications media, especially those dependent on print; rising literacy and education levels; growth of the state; and expansion of popular political participation. In this process, the distinction of public and private took on new importance and complexity. On the one hand, the realm of public interaction expanded; cities were the primary setting for this, especially cosmopolitan trading and capital cities. Public spaces appeared literally with coffee houses, parks, theaters, and other places where people who were not bound by private relations gathered and communicated. They also grew metaphorically with printed sermons, pamphlets, newspapers, books in vernacular languages, journals that reviewed them, and other media of public communication. On the other hand, the state also expanded and with it the range of *res publica*, public things, which included property held in common and matters of concern to the whole polity. Publicness took on a dual sense, referring both to openness of access and interaction and to collective affairs as managed by the state. The public referred both to the collective subject of democracy – the people organized as a discursive and decision-making public – and as its object – the public good.

The two dimensions were linked in the notion that political debate among responsible citizens was a way to arrive at sound understanding of common affairs. This depended on notions of participation in debate that developed in the realms of science and religion (Ezrahi, 1990; Zaret, 1999) and literature (Habermas, 1962; Hohendahl, 1982) as well as politics. Processes of rational-critical debate were held to form educated public opinion as distinct from other forms such as the 'representative publicity' of monarchs appearing before their subjects or the 'mere opinion' of uneducated masses. Interest in such public opinion grew alongside civil society as a self-organizing realm of social relations, and especially with the rise of democracy.

Complementing the growth of the public realm were new senses of the private. The 'privacy' of the family was more sharply affirmed. Women and children were increasingly sequestered in private homes, especially among the bourgeoisie; the modern idea of the individual included the notion of nurturance and maturation in private as preparation for action in public, but this applied in the first instance to men. At the same time, economic activity was increasingly moved out of the household. In one sense, then, going to work meant going out into public, being exposed to the public gaze. In another sense, however, property relations continued to be understood as private in the sense that they were to be managed by individual persons and not the state. The eventual rise of business corporations further complicated the distinction, since these held property as artificial private persons but operated as collective, public actors, especially when shares of ownership were openly available on the market rather than closely held within families.

As the example of corporations and private property suggests, the distinction of public and private was sometimes difficult to sustain. This undermined the classical notion of the public sphere: "The model of the bourgeois public sphere presupposed strict separation of the public from the private realm in such a way that the public sphere, made up of private people gathered together as a public and articulating the needs of society with the state, was itself considered part of the private realm" (Habermas, 1962: pp. 175–176). As corporations became public actors while still claiming the status of private property, states began to intervene ever more into civil society and even intimate life. These trends joined with the rise of mass media, and especially professions and institutions devoted to the manipulation of public opinion through mass media (advertising, public relations) to undermine the conditions for the effective operation of the public sphere as a source for educated public opinion.

History as Decline

For many later analysts, the eighteenth century was a sort of 'golden age' of modern public life (*see* Public Sphere: Eighteenth-Century History). Hannah Arendt (1958) theorized 'public' in terms of creative action, the making of a world shared among citizens, and saw the founding of the USA as a crucial example. Jürgen Habermas (1962) idealized eighteenth-century English parliamentarianism, newspapers, and coffee house conversation. He presented the public sphere as a realm of civil society in which private citizens could communicate openly about matters of public concern, transcending their particular statuses and addressing the state without becoming part of it. Others have focused on Parisian clubs in the Revolution of 1789 (Amann, 1975) or the literary journalism of the German Enlightenment (Hohendahl, 1982).

Idealization of the eighteenth- and sometimes the early nineteenth-century public sphere underwrites explicit or implicit narratives of decline. In Habermas's classic *Structural Transformation of the Public Sphere*, for example, nineteenth- and twentieth-century public discourse is analyzed in terms of the loss of rational-critical capacity attendant on expansion of scale and the rise of public relations management that incorporated the public into the realm of administered society (see also Horkheimer and Adorno, 1944). Such accounts reveal that the notion of public is not only basic to democracy, but also linked to an apparent contradiction in democratic ideals. At least in its most prominent modern, liberal forms, democracy seems to promise both a politics based on reason rather than power, and the inclusion of all adults in the political process. The latter, the classic accounts of the public sphere suggest, undermines the former. The nineteenth- and twentieth-century history of democratic politics is taken to demonstrate this. Public opinion is increasingly 'managed' on the basis of research and manipulation rather than developed in open, rational-critical discourse.

Already in the nineteenth century itself, political theory of many persuasions emphasized the fragility and limitations of the liberal democratic conception of the public. Tocqueville, most famously, argued as early as the 1830s that the democratization of society tended to eliminate the *intermediary* public bodies, which had a traditionally refined opinion and furnished the individual as a collective social identity outside the state. Engaged, politicized publics composed of distinct views and interests could be reshaped over time into mass publics – passive, conformist, and atomized before the state. Tocqueville's fear of the unmediated state would resonate with generations of critics of mass society.

Central to the analyses of historical decline in the public sphere is the idea that as its scope expanded, it was unable to sustain a high level of rational-critical debate. This happened with the rise of various sorts of opinion managers, from pollsters to public relations specialists, and with the institutionalization of political parties as products of negotiations among interest groups rather than arenas for debate about the public good in general. A key phase in this, according to the critics, was the institutionalization of class politics during the late nineteenth and early twentieth centuries. Habermas treated this in terms of negotiation among interests, as distinct from reasoned debate about the public good. Negt and Kluge ([1964]1993), however, famously emphasized the existence of a proletarian public sphere, rooted in distinctive experiences, and productive of reasoned internal discourse. Indeed, the German Social Democratic Party, like successful workers organizations elsewhere, created a parallel public sphere to that dominated by the bourgeoisie (Eley, 1992; see also Katznelson and Zolberg, 1987). This faltered principally because of a nationalization of popular politics, not class politics per se (Mosse, 1975, 1987). Such nationalization was often accompanied by mass spectacle and reliance on mass media. Both did frequently collapse the distinction of public and private, especially in emotive appeals to national unity. Equally important was the rise of two-party electoral systems. Rather than being able to participate activity in public life, late-twentieth-century citizens of democratic societies were reduced to being invited to respond to plebiscites (Lowi, 1985; Ginsburg, 1986).

Historical research on the public sphere has questioned both the accuracy of the late-eighteenth-century ideal and the narrative of subsequent decline. Schudson (1998), for example, has argued that active participation of citizens in public discourse and politics has ebbed and flowed without linear trend. The ideal of the good citizen as an active participant in the public sphere has long been contrasted with the failings of actual citizens. A substantial line of research on 'civic culture' shifted the emphasis away from the problematic of public debate and toward a more general idea of participation and incorporation into civic life, for example, in voluntary associations (see, in particular, Almond and Verba, 1966 and critical analysis in Somers, 1993, 1995). This, as most researchers argued, grew through the nineteenth and early twentieth centuries. More recently, however, critics of late-twentieth- and early twenty-first-century democracies have emphasized a decline in civic participation (e.g., Putnam, 2000).

Participation and Exclusion

Although openness was basic to the ideology and theory of the public sphere, various forms of exclusion were basic to actually existing publics in the nineteenth and twentieth centuries. Women, for example, had been prominent in late-eighteenth-century salon society and elite public spheres, but were widely excluded from nineteenth- and twentieth-century public space; this was mirrored by a commensurate bias in political thought (Landes, 1988; Elshtain, 1993). Feminist struggles made gender a basic political issue in new ways (Ryan, 1990, 1992). In addition, women were prominent in other movements, such as abolitionism in the USA, and may have figured less in subsequent historical accounts than in actual nineteenth-century social movements. This may be partly because of different styles of address in the public sphere, including a greater emphasis on narrative and less on argumentation (Lara, 1999). Similarly, Blacks were largely excluded from the US public sphere, even after abolition. This encouraged a similar duality: struggles for inclusion and development of parallel public discourse marked by distinctive communicative styles (Diawara, 1995).

This has occasioned more general inquiry into 'counter-publics,' which contest the apparently neutral dominance of more mainstream publics (Fraser, 1992; Warner, 2001). This

argument is rooted in Negt and Kluge's ([1964]1993) account of the proletarian public sphere. Members of religious communities, ethnic groups, and the women's movement have been among the many who have constructed counterpublics. During the classic heyday of the late eighteenth- and early nineteenth-century British public sphere, thus, many artisans and workers were denied participation in the public sphere. They were not simply and unambivalently members of a proletarian public sphere, though they did develop their own media and organizations and to some extent constitute a counterpublic (Gilmartin, 1999). They claimed the right to participate in the dominant, unmarked public sphere, and challenged those who introduced restrictive measures to make it a specifically 'bourgeois' (or more generally, propertied) public sphere (Jones, 1983). The same people who excluded those with less wealth from the public sphere nonetheless claimed it in unmarked form as simply *the* British public.

Accounts of the public sphere by both contemporaries and historians have been tacitly linked to the idea of nation, since nation defined the range of citizens entitled to participate in public affairs and the basis for legitimacy of modern, especially democratic, states (Calhoun, 1997). In liberalism's triumphant early phase, experiments in republicanism and constitutionalism placed these issues squarely on the table. They asked how new political structures were to acquire legitimacy and how, within those structures, the plurality of opinion was to be represented. Defenses of free speech and the press, too, signaled an appreciation of the importance of venues in which views could be widely and, in principle, freely circulated. At the same time, the rhetoric of nationalism typically presented the nation not as a creature of public discourse but as a preexisting unity, commonly on ethnic or cultural grounds. This is true even, if ironically, in the USA, the nation quintessentially created through the public action of its citizens. A tension running through American history has pitted the capacity for creation of a new political order exemplified by the founders against claims that the defining national essence is already in place and needs only defense from the loyal.

Notions of a vital republican public sphere have been influential especially in American historical studies, visible in the work of J.G.A. Pocock, Bernard Bailyn, Gordon Wood, and more recently, Michael Warner. Here the focus, in Hannah Arendt's terms, is on the capacity of action in public not only to define individual identity but also to create the world citizens share in common. Republicanism, implied several things: (1) a concerted effort to reach agreement about the public good, as distinct from the attempt to find the net balance of private, individual goods – the essence of utilitarianism; (2) a sense of politics as a work in progress regarding the appropriate structures and limits of the political, as opposed to a hallowed set of procedures for achieving particular ends – such as the cult of the constitution; and (3) a belief that individuality and identity are only fully expressed and enjoyed through engagement in public life, rather than constituted beforehand in the private realm. These writers emphasize the ephemeral nature of republicanism and the rapid emergence in the nineteenth century of a variously liberal, national, and representative (rather than participatory) model of the public sphere. In American Studies, as in Frankfurt School critical theory, this decline is commonly associated with the rise of mass culture – and the blurring of divisions between reasoned political discourse and other social processes of opinion formation.

Cities and Media

Transformations of public life were also shaped by the ways in which communications media and the physical public spaces of cities changed through the nineteenth and twentieth centuries. Richard Sennets (1977) *The Fall of Public Man*, for example, contrasts a vibrant and highly varied eighteenth- and nineteenth-century urban life (especially among the bourgeoisie) to a reduction in both the occasions for interaction across lines of difference and the psychological ability to manage open relations with strangers well. Citizens retreated, Sennett suggests, into both privacy and the conformity of mass culture.

Urban public spaces anchor face-to-face interaction, which was basic to the classical image of the public sphere, conceived of largely in terms of direct interaction. This is important for a sense of serendipitous contact among people of diverse backgrounds. Parks, cafes, and theaters all inform this. Many of Europe's cities, especially older ones, were distinctive in their pedestrian character and their scale. From the mid-nineteenth century, however, this began to shift. Hausmann's post-1848 construction of the Paris boulevards and destruction of some of the local *quartiers* is taken as emblematic (e.g., by Harvey, 1985). Both suburbanization and less pedestrian-friendly, larger-scale designs for newer cities have changed the character of public interaction in Europe, largely in ways familiar earlier in the US Commentators throughout the nineteenth and twentieth centuries have been concerned for the implications of this for democracy. As Mumford (1938: p. 483) wrote, "One of the difficulties in the way of political association is that we have not provided it with the necessary physical organs of existence: we have failed to provide the necessary sites, the necessary buildings, the necessary halls, rooms, meeting places …."

This has been linked to a huge increase in scale. One crucial result is that directly interpersonal relations organize proportionately less of public life; mediations of various kinds have become increasingly important (Calhoun, 1988; Garnham, 1992; Keane, 1991; Thompson, 1995). This is partly a matter of communications media per se; it is also a matter of growing importance for bureaucracies and other formal organizations. The eighteenth- and early nineteenth-century public sphere was closely tied to the spread of print media. The nineteenth and early twentieth centuries were the heyday of great urban newspapers; after this, media that transcended locality became increasingly important. First radio and then television fundamentally altered the public sphere. They contributed to a shift in what was publicly visible as well as in how public discourse was organized (Meyrowitz, 1985; Thompson, 1995). New media shared both information and emotionally powerful images widely. Broadcast media are often charged with furthering the debasement of reason by substituting powerful images for sustained analysis, by appealing to a lowest common denominator in audiences, by blurring the lines between entertainment and critical

discourse, and by centralizing control over messages in the hands of a few corporations. Some caution is in order about generalizations from medium, though, as newspapers produced their own mass forms, with broadly similar if perhaps less extreme effects.

Crucially, the changes in scale and media forms of the twentieth century challenge the classical eighteenth-century model of the public sphere, which was grounded in readership on the one hand and directly interpersonal discourse on the other. Any account of contemporary public life must deal with a dramatic increase in indirect, mediated relationships. Transformations of media continue, of course, and the implications of the Internet and computer-mediated communication are important topics of contemporary investigation (Rasmussen, 2000). Relatedly, the dominant approaches to the public sphere have emphasized domestic politics within nation-states. Especially during the last years of the twentieth century, however, communications media and the rise of transnational organizations have facilitated growth of an international public sphere (Thompson, 1995; Held, 1995; Calhoun, 2002). To what extent transnational public opinion can steer global society directly, and to what extent only through the agency of state structures, remains a crucial question.

Finally, though this article concentrates on the public sphere in Western European and American history, it is important to note that the nineteenth and twentieth century also saw dramatic and transformative growth in public discourses elsewhere. In late Imperial and early Republican China, for example, the category of 'public' became influential and both directly interpersonal and mediated public spheres were created (Wakeman, 1993; Rankin, 1993). This was basic to development of the idea of citizen, as distinct from subject, to constitution of notions of public welfare, and to cultural transformations such as the introduction of new vernacular writing. It also contributed to the growth of both nationalist and class politics in the twentieth century. Further transformations followed, attendant on changes in media, politics, and culture, and creating important linkages within the Chinese diaspora as well as with the West.

An unusually vital print-mediated public sphere developed in India. The early history of this is closely interwoven with the history of British colonialism and opposition to it. The history of Indian public life has been an important setting for examining the role of both international power relations and issues of domestic diversity. Not least, questions like the claims of nonreaders in a public sphere dominated by print media have surfaced and shaped not only Indian but international discussions. Broadcast media have played an important role recently in the constitution of a new Hindu nationalism (Rajogopal, 2001). In many settings, including in the European countries and the USA as well as both India and China, the development of a public sphere has been closely related to the development of national consciousness, identity, and political contestation.

Conclusion

Growth and transformation of public spheres has been a major theme in nineteenth- and twentieth-century history. It is crucial to the history of democratic politics, including not only electoral and parliamentary regimes, but also broader struggles in civil society and beyond national borders. A dominant historical theme is the inclusion of a broader range of participants in public discourse. This has been coupled with analyses of the implications of growing scale, including mismatch between local – especially urban – public spaces and enlarged range of potential participants, dynamics of inclusion and exclusion, and changing roles of media. A prominent line of analysis suggests a concomitant decline in the rational-critical capacity of public discourse. This is challenged by both research on the limits of earlier public spheres and the strengths of later counterpublics. The importance of the public sphere is in any case not limited to argumentation but includes also the formation and spread of culture, as in the development of national identity.

Abstract

Book publishing has been the subject of study by historians, economists, bibliographers, legal scholars, and sociologists. At the junction of culture and commerce, the industry is a focus for researchers interested in issues such as commodification, cultural identity and protectionism, mass versus elite culture, intellectual property, freedom of expression, and business practices. The technology of publishing, from scribal to print to digital cultures, has affected all of these issues. Since World War II, book publishing has become increasingly concentrated, with mergers occurring across economic sectors and national borders, raising questions about organization and cultural protectionism. The rise of digital media has intensified debate about intellectual property law, authorship, and the future of books and reading.

Publishing is the act of making a work of words and/or images available to the public. Book publishing is differentiated from newspaper, magazine, or journal publishing by the nature of the product (volumes in codex form, not published periodically) and its business practices (including royalties to authors rather than single payments, selling mainly through retailers rather than by subscription, and the absence of advertising within the publication). Book publishing encompasses a range of activities through which a manuscript is turned into a printed and bound book or an electronic publication that can be sold or otherwise distributed to an audience. These activities are carried out by organizations and individuals who coordinate creation, production, promotion, and distribution.

History

In the ancient world, texts were reproduced and circulated under the auspices of religious, political, and commercial bodies; in some places, individuals copied and traded books among themselves. During the Middle Ages, publishing in Europe was centered in the monasteries, where manuscripts were reproduced primarily for religious purposes. After the twelfth century, scribes associated with universities took over this task, serving the clergy as well as new readers among officials, the nobility, professionals, and merchants. Until the appearance of the printing press in Europe in 1450, the relevant public was extremely small, limited to those who could read the classic languages and afford hand-copied books. With the advent of print, however, book publishing and bookselling became organized into an industry, its members issuing books in vernacular languages as well as Greek and Latin to sell to a growing and increasingly diverse audience.

Before the seventeenth century in Europe, and the nineteenth century in North America, the book trade remained undifferentiated and unstandardized. A single person usually performed the functions of today's publisher, printer, and bookseller, printing and selling books at the request (and at the expense) of authors or their patrons. Most printers issued newspapers and pamphlets as well as books, and they derived a large portion of their income from job printing of bills, stationery, business forms, and other products. As the market for books grew, a more complex division of labor gradually emerged in some companies, with different segments of the industry responsible for publishing, printing, and selling. (Despite this general trend toward specialization, some large publishing houses continued to do their own printing and maintained retail outlets well into the twentieth century.) Publishers and booksellers also began to specialize in specific types of books, such as school books, religious texts, or medical works.

Within the modern book industry, the publisher is central to the transmission of books from author to reader. Publishing firms select, edit, design, and prepare manuscripts for production; acquire copyrights and sell subsidiary rights such as translation and film rights; create marketing campaigns; sell through wholesale and retail outlets as well as directly to the consumer; and assume the financial risks involved in bringing a book to the public. The publisher interacts and contracts with the author (or the author's representative, the agent). A separate wholesaling sector performs the functions of warehousing and order fulfillment for some publishers. A more differentiated retail sector has also developed, as books are sold through both bookstores and retailers whose primary business is not in books (online and brick-and-mortar); through educational, employment, and voluntary organizations; and through mail-order organizations such as book clubs.

Since the early twentieth century, the publishing industry has been characterized by specialization in response to the markets for particular kinds of books and the channels of distribution. The most visible form of publishing is in trade books, those sold through retailers to a general audience. However, both textbooks (K-12 and college) and titles for professionals (scientific, technical, and medical (STM) publishing as well as books for lawyers, accountants, and educators) are a significant and profitable part of the book market. In many developing countries textbooks make up the single largest segment. Other important segments include the publishers, nonprofit and for-profit, who issue scholarly and religious books. As these divisions between book sectors developed during the twentieth century, different organizational and sales practices appeared within each type of

publishing house. These distinctions have sometimes broken down when mergers have brought together dissimilar publishing houses under a single roof.

The advent of the World Wide Web has reinvigorated the tradition of self-publishing, in which no one performs the gatekeeping or selection process of the traditional publisher. Earlier self-publishers included both authors whose work did not interest mainstream publishers and who availed themselves of the services of vanity presses, and those evading censorship. The latter included most notably the authors of *samizdat* – Russian for 'self-published' – in the Soviet Union. Online publication, which requires no investment in paper or printing, has made it possible for authors to publish their work independently, or with the assistance of an online producer. The willingness of electronic retailers to distribute these books has made the process more attractive and practical.

Publishing as a Field of Study

The world of book publishing has been viewed in various and sometimes contradictory ways: as an elite environment of literary connoisseurs and as a producer of commodified ephemera; as an industrial backwater and as the site of technological transformation; as a promoter of the status quo and as the medium of protest. These contrasting images grow out of the wide range of activity encompassed by book publishing and by the range of disciplines that analyze the industry. Literary scholars focus on trade publishing; scholars interested in education analyze textbook houses; sociologists interested in the transmission of knowledge study university presses and STM publishers. Journalists and people who work in book publishing have joined scholars in studying the ways the industry interacts with the larger society.

Historical Perspectives

Numerous publishers have penned memoirs and histories of individual houses. These, along with the archives of publishing houses, provide primary sources for historians who have sought to provide more analytical accounts of the industry as a whole. 'The history of the book,' which many date to the publication of Febvre and Martin's (1958) *L'Apparition du Livre*, analyzes the production, distribution, and reception of books. Febvre, a prominent member of the Annales school, and his coauthor described early publishing and bookselling in Europe and attempted to account for the book's impact on the spread of various ideas and cultural movements. For some, such as Darnton (1982), the field of research that has evolved since Febvre and Martin's book is equivalent to the social and cultural history of print communication. In this view, the object is to understand the role books have played in society at various times and in various places, and to understand how books have interacted with other social developments and processes. Darnton's proposal is also methodological, suggesting that the book be studied in terms of a communication circuit that runs from author to publisher to printer to shipper to bookseller and finally to reader. The history of the book may also encompass the history of reading: the rise of literacy, the way readers interpret and use books, and the meaning of books in individual lives (for example, Rose, 2001).

Other historians have emphasized the history of printing and the subject of bibliography, that is, the study of books as physical objects. Bibliography is concerned with describing books and identifying their attributes, such as paper, type, and bindings, in order to distinguish different editions or printings. This kind of examination can provide information about particular publishers and manufacturers, about labor practices and productivity, and about authorial intention (see, for example, McKenzie, 1986). The underlying purpose of such studies is to make the book itself the central focus of attention rather than using the book as a means for discovering other social patterns.

Social Science Perspectives

Social science research on book publishing has been intermittent and sparse compared to social scientists' interest in other forms of mass media. Instead, some of the most detailed descriptions and critiques of publishing have been written by people directly associated with the publishing industry. Of course, books and book publishing, central to academic work in the humanities and social sciences, have not escaped academic scrutiny altogether. The state of the publishing world is taken to be a matter of public concern, and scholars and other public intellectuals frequently address a general audience when discussing the significance of developments in publishing for print culture. Throughout the twentieth century, such discussions have often reflected the assumptions of mass culture theory. Commentators question whether publishing practices that cater to a mass market leave room for high-quality books that sell in moderate numbers, and whether increasing commercialism and centralization will homogenize the available literary fare (see, for example, Dutscher, 1954). As this suggests, the curiosity of publishing tends to lie in its dual nature as a commercial enterprise on the one hand, and as a producer of literary objects associated with artistic, educational, and religious values on the other. Indeed, the perceived difficulty of reconciling these two dimensions of publishing – often described as the conflict between culture and commerce – is probably the central problem analysts of the book industry have confronted.

Beginning with work by Escarpit (1958), a relatively small group of sociologists has tried to dissect the workings of the publishing industry. These studies drew on organizational theory (sometimes called the production of culture perspective) which, especially during the 1970s and 1980s, was being applied to various media firms and industries. This perspective begins with the assumption that publishers are similar to other kinds of bureaucratic organizations, facing the same problems of how to reduce uncertainty and risk (Hirsch, 1972). Scholars in this tradition have provided specific accounts of how books are acquired and distributed, and how publishing strategies vary according to size and type of firm. Common to much of this work is a stress on the gatekeeping role that publishers play in determining what new knowledge, theories, and literary forms will enter the marketplace of ideas.

Congruent with trends in mass media and popular culture studies, more recent researchers have reacted against theories of

mass culture and hegemony, which posit audiences as easily manipulated and degraded by mass-market literature. Such scholarship grants the reader a more privileged place in analyses of publishing, both acknowledging the reader's active role in choosing and finding meaning in reading material, and studying how conceptions of the audience shape the work of book professionals. Moreover, this theoretical stance questions the very distinction between popular and quality books. Instead, some suggest that the fear of commercialism has been primarily a cover for the discomfort of cultural elites who see their authority over cultural matters challenged (Long, 1985–1986, Luey, 2010; Radway, 1997). Similarly, it has been argued that publishers play an important role in the production of literary value (Verdaasdonk and van Rees, 1991).

Themes in Publishing Research

Changes within the publishing industry during the last few decades of the twentieth century shaped many of the questions posed in publishing research. Renewed interest in publishing has been concurrent with its integration into multinational entertainment and information conglomerates. Researchers have been especially attentive to the consequences of concentration, the significance of publishing as a global phenomenon, and the convergence between books and other entertainment and information media. Electronic publishing – like the distribution of art and music online – has raised questions of the adequacy of copyright laws and the role of the publisher as gatekeeper.

The Dynamics of Concentration

The American situation best illustrates certain trends in the industry. During the post-World War II era, most major New York publishing houses were transformed from private or family-owned companies into public corporations. Various social changes contributed to this development. The postwar baby boom expanded the market for children's books and textbooks, and many publishers sought to exploit this market by acquiring other houses, creating new juvenile and textbook divisions, or expanding existing divisions. At the same time, the aging heads of publishing houses founded in the first quarter of the century wished to retire. Few had heirs interested in continuing their work. Issuing stock to the public raised capital for expansion and made it possible to transfer a firm's assets in an orderly fashion.

As the assets of publishing houses began to appear in the market in the 1960s, they became attractive not only to other book publishers but also to news and entertainment conglomerates and technology firms seeking synergy. Book publishers would not add much revenue, but entertainment conglomerates hoped that book content could be reproduced across a variety of media, and cross-promotional strategies could be employed. Technology firms believed that the use of television and computers in the classroom would make it profitable to acquire the expertise and content available in textbook publishing. Merger and acquisition activity continued throughout the century, including purchases by foreign-owned companies such as Bertelsmann, News Corporation, and Pearson. The result has been the consolidation of the nation's largest publishers into a handful of companies, which also include American-owned Viacom, AOL Time Warner, and Disney.

Concentration of distribution began somewhat later. Chain booksellers began to grow in the 1960s with the establishment of standardized outlets in shopping malls, but their decisive dominance of the bookstore market did not occur until the 1990s, with the appearance of the superstore. The rise of Amazon.com and its online competitors had drastically altered the retail market by the turn of the twenty-first century. Independent booksellers, already endangered by the chains, virtually disappeared, and the chains themselves were threatened. With the introduction of the Kindle, Nook, and other e-book readers, online booksellers have been able to use their vast market share to bargain with publishers more effectively than other retailers ever could. Amazon.com has also begun to publish original works itself, blurring the lines between publisher and bookseller in a new way.

The effects of concentration have been a constant source of debate. Along with longstanding concerns about declining quality and the homogenization of reading material, these developments raise questions about changes in the organizational culture of the book business. Attempts to rationalize the publishing process, invest heavily in promotion, and exploit new markets have altered the balance of power within the industry, diminishing the autonomy of editors while giving increased clout to accounting, marketing, and subsidiary rights divisions. At the same time, publishers have grown dependent on a few large retail customers who as a result play a more authoritative role in the industry. Complicating the issue of concentration is the increase in numbers of independent publishers and the trend toward self-publishing. Some argue that these trends create diversity at the margins of the industry, and a less-elitist conception of books and publishing at the center. For others, the concentration of control of the book business means that a small number of for-profit companies have undue power over what individuals can read.

Globalization and National Identities

The role that the circulation of books plays in maintaining or undermining specific identities has long been an important theme in publishing research. The concept of globalization is readily applied to the publishing industry: multinational companies with far-flung holdings are now among the major players. But the integration of international markets is the primary way in which publishing can be conceived as a global phenomenon. Since World War II, selling rights to publish or distribute books in foreign territories has become one of the most important sources of revenue for major publishers. The trade in books goes in many directions but disproportionately travels from Europe and especially the United States to the rest of the world.

This raises both theoretical and policy questions about national sovereignty and the maintenance of national identities. In Canada, for instance, the overwhelming presence of first British and then American books has hampered the growth of a national publishing industry. While government policy has helped to preserve Canadian-controlled firms,

foreign-controlled publishers in Canada remain more profitable. Also, many Canadian publishers can survive only because they have the exclusive right to sell American books, which dominate best-seller lists in the English-language market. Even in Québec, where French publishers play a strong role, translations of American books are plentiful. Many argue that this situation has helped to further Americanize Canadian culture, diffusing American tastes, styles, and values through the medium of popular books.

Economic agreements between nations to eliminate trade barriers have, in the past, often excluded cultural products, with books in particular singled out for exception. The 2005 UNESCO Convention on the Protection and Promotion of the Diversity of Cultural Expression reaffirmed the right of nations to control the entry of cultural products from other nations. There are significant obstacles to maintaining a viable publishing industry in less-developed countries, and as the Canadian situation demonstrates, even highly developed nations find it difficult to make the economics of publishing work without protective measures. Internet retailing and online content pose new challenges for cultural control.

Technological Challenges

Trade in books depends on the effectiveness of copyright law, and a significant body of research has examined how copyright and its breach have affected the publishing industry. However, the development of new technologies along with publishing's integration into entertainment conglomerates has raised new concerns about the control of literary property. Content is now easily transportable across media, and entertainment firms attempt to create synergies between book, film, television, music, magazine, and electronic divisions. This introduces a new level of instability into the publishing process. Traditional arrangements for the control of intellectual property are challenged when content is so mobile, with publishers and authors in conflict over who owns the new forms that emerge. The notion that 'information wants to be free,' a rallying cry of the Internet, has intensified pressure on copyright.

The death of the book has been predicted with increasing frequency in the twenty-first century. It is not clear exactly what is moribund. Some see the doom of the codex but assume that the content of books will survive in newer formats. Others fear that the very concept of the book – a reasonably long work of scholarship or the imagination – is threatened, either because creators will not be rewarded sufficiently to motivate them or because new media will so reduce the attention span of readers that there will be no audience. The future of book publishing is thus fraught with uncertainty in technology, law, economics, and culture.

Publishing: Academic and University Presses

Abstract

Since the emergence of the modern university press nearly 150 years ago, these academic publishers have played an essential role in the world of scholarship, not only by making knowledge widely available through the books they publish but also by validating the quality of those books through the process of peer review and by actively engaging with authors to generate ideas for future works. The advent of three relatively new trends – corporate consolidation, globalization, and digitization – has now brought scholarly publishing to a crossroads, and how presses respond to these forces will determine their role in the years to come.

Introduction to University Presses

Academic publishing, and, more specifically, university press publishing, has been a central part of scholarly communications ever since the first books published by the universities of Oxford and Cambridge in the fifteenth and sixteenth centuries. Since the *modern* university press emerged nearly 150 years ago, the number and variety of university presses have proliferated and effectively served the main purpose of illuminating academic issues for researchers and students far and wide, while also playing the functional role of validating the scholarly quality of books through peer review, which is needed by academic authors trying for tenure and promotion. While the title of this article suggests a sprawling subject that reaches into many forms of scholarly communication produced by myriad kinds of publishers, nonprofit as well as commercial, this article will mainly tell the story of the university press itself, particularly of the American university press. Though this may seem like a parochial choice, it is the opposite for two reasons.

First, American university presses sit at the center of a vast international network of scholarly publishers (some university-based, most not), united mainly through translation activities. That is, global scholarly book publishing is heavily defined by the buying and selling of foreign-language rights between American university presses and their fellow scholarly publishers around the world.

Second, as the prevailing model of scholarly publishers, the American university press serves as a sociological and economic model for the debates surrounding scholarly publishers everywhere. As Mark Mazower recently wrote of David Runciman's 2013 history of democracy in crisis, *The Confidence Trap*, "What Runciman's focus on American democracy helps to do is to remind us that there is an international dimension to this subject that is closely connected to American self-perceptions" (Mazower, 2013). This applies to university press publishing as well.

From the early decades of the twentieth century, the period defining the scope of this article, through the 1980s, scholarly publishing at university presses was a relatively stable business. University presses and a handful of commercial scholarly presses produced and published mainly specialized academic books and journals funded primarily by sales to college and university libraries and secondarily by sales to students due to course adoptions. Many presses – notably at state universities such as the University of Texas or the University of California – also supplemented their publishing activity with books of regional or local interest. A certain subset of presses helped finance their operations through the publication of scholarly journals, though books have been the main product of university presses (and so sit at the center of this article).

The distinguishing, even defining, economic characteristic of the modern system of scholarly publishing is that university presses are built to be largely financially self-sustaining. In this regard, they are markedly different than most of their corresponding university-based units such as academic departments, museums, laboratories, or libraries. Aside from certain subsidies and endowment funds, presses have to recover roughly 80% of their costs in order to remain financially viable. Their growth – and their ability to maintain and even expand their annual title output – has been conditioned largely by the budgetary fortunes of higher education in general. As the funding trends have changed, so has the ability of university presses to sustain their title output.

This economic equation changed after the early 1980s with the advent of three powerfully disruptive trends: first, the corporate consolidation of the publishing business at large; second, globalization; and third, digitization and the revolution in information technology. The three-way pressure exerted by these forces on university presses has placed most presses, and indeed the entire enterprise of scholarly publishing, at a crossroads – some would say a crisis point – that threatens the very institution of the university press. How presses respond strategically to these very challenging forces, and how their universities support them in this effort, will determine their future trajectory.

Following some background on their history (where university presses came from) and function (what university presses do), this article will take up these forces and consider the cumulative effect they are having on the university press and its commercial corroborates.

A Thumbnail History of Modern University Presses

The historical impact of university presses can best be understood in three ways: first, through a chronological accounting

 http://dx.doi.org/10.1016/B978-0-08-097086-8.41035-4

of presses themselves; second, through their publications; and third, through their people.

The Evolution of University Presses

The ancient history of the modern university press originates with Oxford and Cambridge vying for primacy in the fifteenth century, joined briefly by Harvard in the seventeenth. The story begins in 1478 when Oxford published a commentary on the *Apostle's Creed*, followed in 1521 by the establishment of a university printer in Cambridge. In 1640, on the other side of the Atlantic, Harvard University, then only 4 years old, issued the *Bay Psalm Book*.

But according to Peter Givler, former executive director of the Association of American University Presses, the modern character and personality of university presses only developed in the latter part of the nineteenth century with the establishment of The Johns Hopkins University Press, just 2 years after the university was founded in 1878. Unbeknownst to him at the time, Hopkins founder Daniel Coit Gilman gave university presses their motto when he wrote, "It is one of the noblest duties of the university to advance knowledge, and to diffuse it not only among those who can attend the daily lectures, but far and wide."

Gilman and the Hopkins leaders also gave university presses their structure, describing the press as a publishing house operating under the nonprofit charter of the university and charged with publishing the results of postdoctoral research.

The Johns Hopkins University Press was followed in 1891 by the establishment of the University of Chicago Press, 2 years after that university was founded. Two years after that, both Columbia University and the University of California began their presses.

The business of scholarly book publishing grew over the next several decades with the appearance of the University of Toronto Press in 1901, Princeton in 1905, Fordham in 1907, Yale in 1908, Washington in 1909, and Harvard in 1913 (following the closing of its original press in 1692). The second decade of the twentieth century closed out with the establishment of NYU in 1917, Stanford in 1918, and Illinois in 1919.

As university presses grew over the ensuing decades, they eventually came together in the establishment of the Association of American University Presses (AAUP) in 1946. The founding of the AAUP preceded the great boom in twentieth-century university press publishing, marked by the beginning of the race for space triggered by the launching of Sputnik in 1957. America's government, determined to meet the Soviet challenge, began investing massively in science and in research in other areas of higher education. Scholarly book budgets grew, and funds flowed to their publishers, especially university presses.

As much as the mid-century growth of university presses was marked, ironically enough, by outer space with the 1957 launching of Sputnik, it ended there too, with the Apollo 1969 moon walk of US astronaut Neil Armstrong. University press growth began to level off with the ebbing of the Cold War as government funding for publisher-produced research declined. This reduction in funding has continued gradually but steadily since then, beggaring the library market for scholarly monographs, the main stock in trade of university presses. The response on the part of presses, adapting to the realities of a withering market for their books, would stamp their history until today. (The foregoing discussion is based on Givler, 2002.)

As Cold War library funding began to dry up, university presses began to diversify. Fortunately for presses, the opportunity to do so coincided with consolidation in commercial publishing, the first factor to give the modern university press its shape. This consolidation would reconfigure the map of scholarly publishing largely in favor of university presses, and it has played into the hands of university presses at two levels: text and trade. Some university presses, in an effort to generate funds from greater sales, began to publish more trade books – that is, books intended for a broader cross-disciplinary, and even public, audience – and textbooks. Many university presses stepped into the advanced, first-year PhD level courses largely abandoned by commercial college publishers seeking greater fortunes by publishing for large introductory courses. This move to diversify the portfolio of university press publishing output would show up impressively in some of the outstanding titles produced during this era.

Important Contributions of University Presses

A brief (and informal) sampling, dating from the days around the establishment of the AAUP in 1946, suggests the extraordinarily, and too often forgotten, scholarly and literary legacy of university press publishing.

Some of the greatest university press books published graced the social sciences and include the following:

- Friedrich Hayek, *The Road to Serfdom* (Chicago)
- Milton Friedman, *Freedom and Capitalism* (Chicago)
- Daniel Patrick Moynihan and Nathan Glazer, *Beyond the Melting Pot* (MIT)
- David Reisman, *The Lonely Crowd* (Yale)
- Robert Shiller, *Irrational Exuberance* (Princeton)
- Robert Bellah et al., *Habits of the Heart* (California)
- Carol Gilligan, *In Another Voice* (Harvard)
- Thomas Piketty, *Capital in the Twenty-First Century* (Harvard)
- Albert O. Hirschman, *The Passions and the Interests* (Princeton)
- Alfred Chandler, *The Visible Hand* (Harvard)
- Richard White, *The Middle Ground* (Cambridge)
- Paul Samuelson, *Foundations of Modern Economic Analysis* (Harvard)

The humanities sit at the heart of the university press publishing portfolio, and it is there that university presses have made some of their greatest impact. Among the most outstanding humanities titles one thinks of the following:

- Mark Girouard, *Life in the English Country House* (Yale)
- E. H. Gombrich, *Art and Illusion* (Princeton)
- Jacques Derrida, *Of Grammatology* (Johns Hopkins)
- Northrop Frye, *Anatomy of Influence* (Princeton)
- Harold Bloom, *Anxiety of Influence* (Yale)
- Camille Paglia, *Sexual Personae* (Yale)
- Paul Fussell, *Great War and Modern Memory* (Oxford)
- T. Harry Williams, *Lincoln and His Generals* (LSU)
- Peter Brown, *Augustine of Hippo* (California)

- Mary Beard, *The Parthenon* (Harvard)
- Terry Eagleton, *Literary Theory* (Minnesota)
- John Rawls, *A Theory of Justice* (Harvard)
- Richard Rorty, *Philosophy and the Mirror of Nature* (Princeton)
- Charles Taylor, *A Secular Age* (Harvard)
- Harry Frankfurt, *On Bullshit* (Princeton)

Science is not thought of as a core university press publishing area, yet it has produced some of the most influential and enduring university press books:

- Albert Einstein, *The Meaning of Relativity* (Princeton)
- Thomas Kuhn, *The Structure of Scientific Revolutions* (Chicago)
- Richard Dawkins, *The Selfish Gene* (Oxford)
- Claude Shannon, *The Mathematical Theory of Communication* (Illinois)
- Linus Pauling, *The Nature of the Chemical Bond* (Cornell)
- Stephen Jay Gould, *The Structure of Evolutionary Science* (Harvard)
- E. O. Wilson, *Sociobiology* (Harvard)

University presses are hardly thought of as publishers of original literary and cultural works, but here again their output has been impressive. Highlights include the following:

- Eugene O'Neill, *Long Day's Journey into Night* (Yale)
- John Kennedy Toole, *Confederacy of Dunces* (LSU)
- Bohumil Hrabal, *Closely Watched Trains* (Northwestern)
- Ted Kooser, *Poetry Home Repair Manual* (Nebraska)
- John Neihardt, *Black Elk Speaks* (Nebraska)
- Norman McLean, *A River Runs Through It* (Chicago)
- Carlos Casteneda, *The Teachings of Don Juan* (California)
- *The I Ching* (Princeton)

Last but not least, in reference, university presses sport perhaps the most iconic book in all of publishing, *The Chicago Manual of Style*.

University presses tend to be talked about in terms of the quantity of the books they publish. The aforementioned list makes an impressive case for their quality.

What Do University Presses Do?

The story of scholarship in the twentieth century and beyond, especially in the humanities and the social and behavioral sciences, can be told largely through its books. University presses have figured powerfully in creating this story. From the early days of the university presses, they have brought the seminal work of authors such as Albert Einstein, Woodrow Wilson, Thomas Kuhn, David Reisman, William McNeil, Martha Nussbaum, Henry Louis Gates, Robert Shiller, and Thomas Piketty to market, and they continue to do so. And yet presses have done much of their work quietly and with little understanding on the part of observers of what actually happens within their walls. A brief accounting will help clarify their function within the culture of scholarly communications.

A few basics are in order: First, all university presses are nonprofit publishing entities either owned by or closely affiliated with their host universities. Second, university presses publish only peer-reviewed books, evaluated and accepted by panels of professors within their host universities, which are called editorial boards, faculty committees, or some variation thereof. Third, university presses are structured largely along the lines of their counterpart commercial publishers. That is, they are led by a director (historically an acquisitions editor promoted from within the ranks), and they employ acquisitions editors who acquire and build their lists of books, production teams (including production coordinators and designers) who create these books, marketing departments (including publicists, sales staffs, and direct mail and Web marketers) who sell the books, contracts departments, foreign rights departments, finance and administration departments, and in many cases entire warehousing and distribution departments that house and distribute the books.

The engine that drives the university press and that shapes its scholarly output is editorial acquisitions. Editorial acquisitions departments, typically headed by an editor-in-chief (or, at smaller presses, the director), are organized to generate a strong and steady supply of books in each area in which the press publishes, typically at most presses some combination of history, a cluster of humanities disciplines, and various social and behavioral sciences. Not surprisingly, university presses have traditionally organized their acquisitions efforts around those fields where books (as opposed to journal articles) form the foundation of academic knowledge while also serving as the basis of tenure and promotion decisions for their authors. Most great university press lists consist of a portfolio of books that include not only the works of mid-career and senior scholars, but also critically of junior scholars seeking to build their literary output and secure their career trajectories.

The Editorial Imagination

Acquisitions Editors

Within universities most discussion of university presses revolves around their instrumental functions: title output, revenues and costs, production capacity, and the practical value of the press in verifying the quality and kind of monographs as a basis for tenure decisions. The press is seen in this formulation as a relatively passive agent in the scholarly process. Yet the impulse that defines and drives the university press, and gives it life and personality, is what might be called the editorial imagination.

By applying their command of ideas and enthusiasm for cultivating ideas, acquisitions editors actively play a vitally important role in the propagation of scholarly knowledge. Acquisitions editors, often self-educated in the academic cultures of the fields in which they publish, reach out to scholars through university travel and conference attendance to create the author networks that attract the books to their lists. Further, these editors actively suggest and work with prospective authors to generate ideas for books. Examples abound, but a recent and significant example is the widely admired *Princeton Companion to Mathematics*, initially inspired by Princeton University Press editor David Ireland. Another is *The Classical Tradition*, initially suggested by Harry Haskell at Yale University Press. Series, such as The Princeton Economic History of the Western World, also came about because of the initiative of

acquisitions editors. This activity, centrally important to the development of outstanding publishing programs, is the engine that drives the university press.

The application of the editorial imagination contributes to the distinctive and diverse character of university press publishing. Each list is different and reflects the taste and intellectual curiosity of its editor. Some of the outstanding recent lists are Lindsay Waters' humanities list at Harvard University Press, Douglas Mitchell's sociology list at Chicago, Patricia Fidler's art and art history list at Yale, Roger Conover's cultural studies list at The MIT Press, and the economics list that several of us have built at Princeton. Other editors who have distinguished themselves in past years are the late Sheldon Myers, history editor at Oxford University Press in New York, Susan Abrams, who built the history of science list at Chicago, Marian Ash for her political science list at Yale, and Terry Moore, philosophy editor at Cambridge.

While acquisitions editors serve as the university press's main conduit to the outside world of authors, they also lead the system that connects these authors and their books to the internal staff of presses. These members then communicate with external corresponding communities vital to the propagation of scholarly ideas. Acquisitions editors 'publish their books within the press' to the production editors, designers, and copywriters who shape and structure books. They are also responsible for coordinating book releases with publicists and foreign rights directors, who communicate the virtues of books to the scholarly community. Publicists pitch to the vital networks of book reviewers, journalists, and periodical editors and producers responsible for reviewing and discussing books in their publications; rights directors pitch the books to scholarly and commercial foreign-language copublishers around the world for translation. This publishing circuitry, structured around the imagination and initiative of acquisitions editors, sustains the scholarly book publishing enterprise.

Marketing and Sales

Publishing the book within the press also requires acquisitions editors to coordinate with marketing and sales departments. This means equipping these colleagues with the necessary information for marketing to create the Web pages, direct mail pieces, and advertising necessary to engage prospective buyers, e.g., researchers, librarians, and faculty adopting books for courses. Meanwhile, supplying book information to sales directors and their staff makes it possible for these colleagues to actively pitch distributors and booksellers – local, chain, and online – on the press's forthcoming publications. Increasingly, university press sales departments have developed relationships with online aggregators such as Books at JSTOR, Project MUSE, and Walter de Gruyter, which supply research libraries with digitized collections of scholarly books from many publishers. This activity is finding new expression in e-book lending to public libraries through firms such as Overdrive and subscription services such as Oyster.

Further, most university presses maintain relationships with certain overseas sales representatives and agents (often serving small groups and press consortia, such as the University Press Group in Europe or Zhao Wei in China), who sell to local distributors and library wholesalers on information provided by university press sales directors and supported by reviews and other promotion generated by press publicists.

Completing the circle, actively engaged acquisitions editors cull feedback from these various sources to help inform themselves – and by extension, their authors – of the changing landscape of global scholarly book readership; what works, what does not work, and why.

Publishing Culture

Beyond the publishing process sparked by the engaged imagination of acquisitions editors, university presses operate at the intersection of several networks that help define their distinctive role in the scholarly and publishing cultures. Formal relationships include membership in the AAUP, the Association of American Publishers, and the International Publishers Association. These organizations convene to address issues bearing on the viability and health of their members and to address communally important issues such as copyright and piracy, while also providing educational services for member publishers.

Informal relationships include ongoing correspondence and meetings with foreign publishers with whom university presses meet regularly at the Frankfurt, London, and Beijing book fairs. Included in this category are organizational relationships American university presses have developed with mirror organizations in China, South America, Europe, and Japan. Finally, this constellation of corresponding organizations also includes related associations such as the Association of American Research Libraries, the Association of American Universities, and the American Library Association. It is within this institutional network that university presses advance the agenda for their ongoing contribution to knowledge.

Three Forces Reshaping the University Press

Neil Armstrong's walk on the moon may have marked the end of steady, predictable, and perhaps even complacent growth on the part of university presses. But three forces closer to Earth, all mentioned at the beginning of this article – corporate consolidation in publishing, globalization, and digitization – have shaped the recent history of university press publishing in equally profound ways, for better and for worse.

Corporate Consolidation in Publishing

What could the first of these forces, corporate consolidation in commercial book publishing, have done to the university press? Plenty. With the market for scholarly monographs slowly and steadily in decline by the early 1980s, university presses began to look around for ways of supplementing their revenues while remaining within the scholarly idiom. Changes in commercial publishing would provide the means. At the time, commercial publishing began a historic consolidation that would streamline what once had been a large and diverse business into a handful of megacorporations. The economies achieved in this transformation occasioned changes in two parts of commercial publishing in particular that would

provide opportunities for university presses: crossover nonfiction and college publishing, and to a lesser degree specialty publishing (including regional books).

Crossover nonfiction publishing is that part of the business most associated with houses such as Basic Books, The Free Press, Pantheon, Athenaeum, and a few others. From the World War II onward these houses thrived on the strength of publishing outstanding intellectuals for broadly cross-disciplinary and even general readerships (hence the term 'crossover'). This style of publishing is most prominently associated with Basic Books, which in the 1970s reached its apogee in the works of Robert Nozick, Michael Walzer, James Q. Wilson, and others. After the 1980s, these crossover houses and others came under pressure from the corporations that owned them to produce greater growth and higher profits through a steady supply of best sellers than typically associated with their traditional publishing. As a result, many authors, and even some editors, who would have published with or worked for one or more of the crossover houses migrated to the university presses. The presses that most benefited from this migration were the big Ivy League presses and the University of Chicago Press, each of which successfully built up its crossover publishing by signing major authors who might otherwise have continued to publish with commercial crossover presses. The most recent example is Thomas Piketty's extraordinarily influential 2014 book, *Capital in the Twenty-First Century*, published by Harvard. And while riskier and more expensive, this style of publishing provided the university presses capable of doing it with a new revenue stream.

A similar shift took place with college publishing. The concentration that occurred in college publishing was dramatic, resulting in the reduction in the number of college publishers from around 30 in the early 1970s to only a handful – five or six major higher education houses – by the late 1980s. Corporate pressure in college publishing came in the form of a powerful concentration on introductory and intermediate-level textbooks, central to big enrollments and potential big revenues. This concentration opened up the smaller upper-level undergraduate and graduate course markets for publishers at the business's margins. Certain university presses were only too happy to step in, first and most notably MIT Press, which pioneered the art of the excellent advanced textbook in technical areas such as economics and computer sciences. Other university presses followed suit, integrating the advanced textbook into the broadening portfolio of scholarly books.

For many state university presses, this exercise in portfolio diversification arose not from textbooks, but from another source: regional books. These books included kinds of titles once associated mainly with the ever-concentrating business of commercial publishing, such as books on cuisine, architecture, design, natural history, and sport. These genres, embraced by university presses from Rutgers in New Jersey to the University of Hawaii Press, have supplemented presses' more mainstream scholarly publishing while enriching the cultural lore of their home cities and states.

Globalization

The opportunity for diversified publishing occasioned by the commercial consolidation of publishing in the 1980s, and the concomitant search for new sources of growth on the part of university presses, helped to preserve some very important strains of publishing while strengthening university presses and animating their lists. Globalization, the second of the forces under discussion, would have similarly salutary results for those university presses prepared and poised to take advantage of it.

Declining library sales – historically the mother's milk of scholarly monograph publishing – combined with a drop-off in independent bookstore business to advance the steady desiccation of the domestic market for scholarly books in North America. The domestic bookstore market staged a rally in the 1990s with the rise of chains such as Borders and Barnes & Noble, but this trend was short-lived, owing to the increasing dominance of Amazon and online book shopping. The net effect was a gradual but dramatic reduction in the amount of shelf space available for scholarly books – and hence a further shrinkage contributing to the now generation-old decline of university presses. Presses would shore themselves up not only through diversification of their publishing portfolios but also by looking for new readers in new places: this meant overseas, an opportunity accompanied by the globalization of higher education.

Setting the stage for the globalization of the university press are several forces: the growth of the developing world, the spread of English as the lingua franca of scholarship, the rise of cross-national scholarship, the investment in higher education among governments in developing countries, and the growth of literacy rates around the world. Concomitant with the expansion of global markets has been the corresponding growth and integration of the media, giving publishers access to book reviews, editorial pages, and eventually blogs and social media as conduits of exposure for news about university press books.

Leading the way in accessing these global markets have been those presses with lists that 'travel,' meaning clusters of books in areas such as science, economics, philosophy, and world history that appeal as greatly across other continents as they do in North America. Among the most prominent global presses are Princeton, spurred by its economics list since the 1990s; Yale, strategically well placed to grow internationally through its London office, established in the 1970s; The MIT Press, well situated in globally relevant science fields; and smaller presses such as Georgetown and Fordham with their strong lists in languages and international culture. Sales of English-language editions of university presses for globally minded presses have been abetted by expanded translation business, especially in growing countries such as China, Korea, and Brazil.

Globalization continues to provide a source of residual growth for university presses, especially those deploying strategies around the development of editorial programs geared toward international readerships.

Digitization

The final force in reconfiguring the university press, digitization, has had both positive and destabilizing effects on presses. While university presses tend to be regarded by university administrators and librarians as technologically old-fashioned institutions, presses actually were early movers in

implementing digital technologies, blazing a trail in book production through the use of digital files in the copyediting and typesetting of their books. By the early 1980s, digital book production had become the norm across university press publishing, while the use of computer technology had begun to spread throughout the other functions across the business. As the quality and sophistication of digital technology grew, the digital production of university press books evolved.

The next turn in this evolution came with the rise of the Internet, which enabled presses to apply digital technology as a means of communication. The Internet made it possible for university presses to reach out to book review editors, editorial page editors, critics, journalists, and public intellectuals writing for publications all over the world. This global publicity landscape was later enriched by blogs, and eventually by social media. Presses that held world rights to their books could, and did, constructively pursue global publicity and review coverage for their books, occasionally resulting in worldwide sales success.

Global university press publishing took its next step on the sales front with the spread of online book merchant sites such as Amazon and The Book Depository as well as national sites such as Flipkart in India. Readers in countries serviced by these sites were able to discover and purchase university press books with greater ease than ever before. Meanwhile, the rise of library aggregators made possible the online purchase of university press books by libraries around the world, including university library consortia in developing countries, which were able to acquire complete collections of dozens of university press offerings at minimal prices and make them freely available to researchers in their networks.

While corporate consolidation and globalization have been unambiguously positive influences on the university press, digitization is a much more complicated story. On the one hand, it has enabled presses to be far more effective in reaching markets and making their books discoverable than ever in their history; on the other, it has created pressure from parent institutions to push presses into making their publications freely accessible on the Web without accounting for the operating costs that make the publication of books possible in the first place. This is the crossroads noted at the beginning of this article, and its resolution will define the fate of scholarly books in the next generation.

The underside of digitization for university presses and other book publishers is captured in Joseph Schumpeter's (1942) notion of creative destruction – that is, technological innovation itself contains the seeds of institutional subversion. This Schumpeterian subversion has come to scholarly book publishers in two forms: via outside attack by digital piracy and via institutional pressure through universities' calls for open access to books.

Online book piracy, though seemingly a recent plague for publishers, is as old as online publishing itself. Dating back to the early 2000s, online pirate sites such as Pirate Bay have captured book files from university presses and commercial publishers alike, making these files freely available to prospective readers all over the world. Individual publishers as well as national associations of publishers have endeavored to immobilize pirate sites by legal threats and even by legislation against Web providers that host pirates, but efforts to this day have been largely ineffectual. Estimates place the losses from piracy to publishers at around a tenth of net revenues.

While piracy amounts to a direct assault on university presses and their authors through copyright violation, digitization presents another threat to university presses and the cost-recovery economic model on which they operate by way of 'open access.' Open access is the name of a movement, championed by some university leaders, librarians, academics, and foundation executives, for presses to make their books freely available on the Web. Although there have been ideas proposed for university funding of open access university press books, nobody has yet devised a way to effectively underwrite university presses while offering their books free of charge.

An intermediate disruption caused by digitization appeared a few years ago in the form of a challenge to the fair use of published materials in the classroom. The crux of this challenge arose in a dispute between universities, which embraced a broad interpretation of fair use in order to make copious amounts of published materials available to instructors for use as classroom materials, and publishers, who hewed to a more limiting interpretation of fair use. This issue is still being adjudicated in the courts, just as the influence of digitization on university presses continues to evolve.

Challenges to the Future of the University Press

As noted at the outset of this article, university presses are poised at a crossroads. How they frame the value of what they do, how this value is perceived by university leaders, and how the presses enhance their value proposition in the future will determine their fate. There are basically two scenarios surrounding this value proposition – a low road and a high road. The low road charts a diminishing role for university presses. It defines presses in minimal terms, casting them as little more than third-party credentialing agents for tenure candidates at colleges and universities near and far. This function can and will – and, some would argue, should – be performed by educational institutions themselves, largely on the Internet. The university-based library publishing movement now taking shape is a first step in this direction.

The high road for university presses traces a different future. The high road casts university presses less as passive credentialing agents than as active publishers, purposefully engaged in shaping the scholarly conversation and in reshaping publishing itself. The high-road university press is an editorially driven publishing enterprise in which editors are actively working with authors to develop ideas for new books of various kinds – monographs, textbooks, trade books, and reference works – while the leadership of such a press seeks new ways to connect its books to the scholarly world at large and especially internationally, through traditional print as well as technologically advanced media.

The high-road university press eagerly engages other parties in the global republic of letters – book reviews, editorial pages, syndication services, bloggers, and public intellectuals – in framing and airing the scholarly conversation.

The high-road university press actively builds the narrative of scholarship, across disciplines and around the world, extending fully into the developing world. Ultimately, it will find a way not only to engage, but also to cultivate the next generation of scholars, both from the industrialized and the developing world.

Punishment

Claire EM Hamilton, Queen's University Belfast, Belfast, Northern Ireland, UK

Abstract

Given the focus elsewhere in this collection on the comparative politics and functions/history of punishment, respectively, this article focuses on the meaning of the concept itself. The legal prerequisites for formal punishment will be discussed before proceeding to examine its main components, namely, censure and sanction. The final two sections critically discuss the traditional view that punishment comprises a sentence imposed by a criminal court following a conviction.

Legal Requirements and Justification

Despite its popular usage as a term for anything, which is painful or demanding, formal punishment in the sense that interests lawyers and criminologists denotes penalties authorized by the state in response to a criminal offense. This has been further elaborated by Hudson (2003: 1–2) as a set of six criteria, adapting work done by philosophers, Flew (1954) and Benn and Peters (1959):

- It must involve an evil or the infliction of some unpleasantness.
- It must be for an offense, actual, or supposed.
- It must be of an offender, actual, or supposed.
- It must be the work of personal agencies.
- It must be imposed by an authority conferred through or by the institutions against the rules of which the offense has been committed.
- The pain that is inflicted should be intentional, not accidental or coincidental.

Clearly, the authority averred to in the fifth criteria is a judicial authority in the form of a court and the institutional rules are the rules of the criminal law and penal system. Zedner (2004) additionally draws attention to the foundational legal principles that protect citizens from arbitrary prosecution and sentencing, namely, "there can be no crime without law" and 'no punishment without law.' While, as will be seen below, this narrow view of punishment as pain inflicted following conviction by a criminal court should not be accepted uncritically, the above remain the prerequisites of formal or legal punishment in many contemporary Western societies. The systematic study of punishment following crime, together with the study and evaluation of penal institutions, can also be said to form the basis for the field of 'penology,' though this is arguably a term less in common usage now than previously (Hudson, 2003; Sparks, 2013).

Broadly following Zedner's (2004) discussion of punishment in the context of criminal justice, discussion below will focus on 'censure' and 'sanction' as component parts of punishment, as well as revisiting traditional notions of punishment as pain delivered by the state at the end of criminal process. Given their treatment elsewhere in this collection (*see* Punishment: Comparative Politics of; Punishment: Social and Legal Aspects), the social roles of punishment and the various philosophies of punishment will not be comprehensively dealt with here. Suffice it to say at this juncture that the former has assumed a growing importance within penology in recent years, replacing the positivist 'punishment' with the more constructivist 'penalty' viz. the complex of ideas, institutions and relationships that deploy, construct and legitimize the power to punish (Garland and Young, 1983). The latter are generally divided into two groups, with the major point of distinction being their prospective or retrospective orientation. Theories such as retribution and denunciation differ from the rest of the rationales for punishment in that they are deontological and backward looking in their outlook (Von Hirsch, 1993). Punishment is gauged in relation to the harm caused by the offense and culpability of the offender. Instrumentalist or utilitarian theories such as deterrence, rehabilitation, and incapacitation, on the other hand, are forward looking, i.e., they hope to achieve something through punishment. They are also often referred to as consequentialist because they seek to justify punishment in relation to its anticipated future consequences (Braithwaite and Pettit, 1990) or reductivist because they aim to reduce crime (Cavadino and Dignan, 2012). In considering, and indeed seeking to reconcile, the various rationales, it is useful also to bear in mind another distinction, namely, that between the general justifications of punishments and the principles of distribution (Hart, 1968). Many people would accept that the overall aim of the system of punishment is preventative or deterrent, but this does not answer key questions about how much punishment there should be for certain types of offences/offenders and what types of punishment there should be – arguably, concepts such as desert or proportionality best supply the answer to these questions. The tensions between the various schools of thought may be easier to resolve, if this hybrid approach is adopted as a starting point.

In discussing the philosophical basis of punishment, consensus should not of course be assumed. The work of the abolitionist movement presents an important challenge to mainstream penology given their arguments that, far from reducing crime and protecting the public, the criminal justice system engenders further criminality, reproducing social divisions. While sometimes dismissed as 'sociological dinosaurs' (Sim, 1994), abolitionist criticisms have been highly influential

in moderate penal policies in Scandinavia and the Netherlands and indeed, can be viewed as the conceptual forerunners of what would become the restorative justice paradigm (Snacken et al., 2013).

Censure and Sanction

Moving to the essential elements or characteristics of punishment, these have been identified by Zedner (2004) as censure and sanction. Censure or condemnation of an individual's actions forms an essential element of punishment, giving further, more forceful expression to the censure already conveyed by a criminal conviction. This idea is closely allied to the notion of communicative or expressive punishment or indeed its 'symbolic significance' (Feinberg, 1994: 74). Thus, for example, a fine imposed as punishment carries a censure or condemnation that a civil penalty such as a tax does not, even though both are payable to the state. Much work has been done on censure by retributivists such as Andrew von Hirsch given their emphasis on punishment as the expression of blame or a moral judgment on an individual (Duff, 1986; Von Hirsch, 1993; Narayan, 1993). In *Censure and Sanctions*, von Hirsch argues that censure is addressed not only to the offender but also to the victim and others in society:

- Offender: it sends the message that society disapproves of what she/he has done and that a moral response is expected;
- Victim: it acknowledges the victim's hurt and loss and that this occurred at the hands of the perpetrator;
- Society: it provides reasons for desistance from wrongdoing, not because they fear the consequences but because it is morally wrong.

Assuming censure was sufficient to these tasks, questions may legitimately be raised about the justification for inflicting further pain in the form of a sanction on the offender. Punishment involves deliberately harming individuals, and therefore stands in very strong need of justification (Lacey, 1988). Von Hirsch (1993) and Narayan (1993) answer this question by arguing that the sanction acts as 'prudential disincentive' or reason for the offender to resist temptation and pursue the proper course of action. This supplements rather than replaces, however, appeals to the individual's moral sense of the wrongfulness of the act and it should be noted that the sanction must comport with the seriousness of the crime so as to reflect the appropriate degree of censure. At the other end of the spectrum, Braithwaite and Pettit's (1990) republican theory of criminal justice seeks to decouple censure from sentencing. On this view, censure may be achieved more effectively by reintegrative or nonstigmatizing shaming or other forms of social intervention. This is not predicated on abstract notions of individual responsibility, however, and the idea of proportionality is also rejected.

Turning now to the 'sanction' aspect of punishment, questions arise about the defining element of this pain-causing activity. Does the importance of the pain or unpleasantness imposed reside in the intention of the person imposing the sentence or the experience of the person receiving it? Some theorists prefer the former interpretation, with Hudson (2003) citing Walker (1991: 3) that "it is the belief or intention of the person who orders something to be done and not the belief or intention of the person to whom it is done that settles the question whether it is punishment." Walgrave (2004: 48–49) similarly distinguishes between, on the one hand, fines and incarceration as punishments or 'intended deprivations' and, on the other, probation or 'reparative measures' as nonpunishments or measures that are 'intended to be constructive.' Yet, to exclusively privilege the intentions of the sentencer over the sentenced in the punishment process also presents difficulties. The story reported in Cork, Ireland of two homeless brothers who threw a stone through the window of a bank because they could not cope with sleeping rough demonstrates well that for certain types of offender, punishment may be experienced as a benefit (Kilcommins et al., 2004). Kolber (2009: 214) also makes a compelling argument for recognizing subjective experience in calibrating punishments, arguing that "it is this very concern about inflicting distress that leads us to seek a justification for punishment in the first place."

The centrality of pain to the notion of sanction raises further questions about whether punishment loses its punitive quality where it imposed for the purpose of doing good. Arguments such as those referred to above by Walgrave have been challenged by writers such as Davis (1992), Crawford and Newburn (2003), and Levrant et al. (1999), in the context of a discussion of whether outcomes from restorative justice process are types of punishment. On this view, punishment includes anything which is a burden or imposition on the offender; the intentions of the sentencer are not relevant. While clearly claims about 'doing good' should be treated cautiously, research with sentencers often reveals rehabilitative intentions behind the ostensibly 'harsh' decision to sentence an individual to a term of imprisonment. McAra (2011: 100), for example, discusses research with Scottish sentencers suggesting that "prison (no matter its brutalizing reality) has been successfully marketed as a therapeutic institution capable of delivering reintegrative programmes." Imprisonment was thus in this context not always a punitive choice. The objective and subjective meaning of a related, but distinct, term, 'punitiveness' (see Pratt et al., 2005 among others on the 'new punitiveness') is an issue, which has recently received some attention from criminologists such as David Nelken (2005). He writes "are we mainly interested in the causes and conditions of variations in levels of punishment, regardless of the intentions of those involved? Or are we trying to explain why members of a given society think they are being punitive or non-punitive?" (2005: 221). Continuing in this vein, Nelken (2009) seeks to unpack assumptions commonly made about 'punitiveness' and 'leniency' in Italian-English youth justice. These countries are often put at opposite ends of the punitiveness spectrum in terms of their youth justice systems and are often characterized as 'lenient' and 'punitive,' respectively. Yet, researchers often fail to engage with what policymakers and other actors think they are doing and why it makes sense *to them*. Nelken notes that legal actors in the English and Welsh youth justice systems simply claim to be doing their best for young people before they get into further trouble and that "different working assumptions lie behind the levels of tolerance or leniency in dealing with young people in different places. In England and Wales it is thought that children will not easily grow out of delinquency without official intervention. In Italy, on the other hand, there is a legally enshrined presumption that in the majority of cases they will do

so" (Nelken, 2009: 307–308). His argument, therefore, is that in addressing questions of punishment, the researcher needs to keep the objective and subjective aspects distinct: it is important to differentiate between the deliberate infliction of pain/leniency and that which is motivated by other (worthy) concerns or the product of neglect. In an increasingly complex penal environment, 'punitive' outcomes can occur for 'good' reasons and vice versa (Daems, 2007).

A related point may also be made about community sanctions, which are often perceived by the public in relatively lenient, nonpunitive terms. The misperception (termed by Von Hirsch (1993) as the 'anything but imprisonment fallacy'), however, is revealed in research by Hudson (2006) and others (e.g., Dumortier, 2003) on the highly 'punitive' effects of interventions such as treatment programs and restorative justice. For some offenders, treatment programs in a noncustodial environment may be experienced in a very punitive manner given their demands on their privacy and the 'secrets of the self.' Recent work by Durnescu (2011) has very usefully attempted to identify more precisely the 'pains of probation' ranging from deprivation of autonomy to stigmatization effects through to the financial costs of attending meetings with their probation officer. The punitive ethos of many of these orders is also revealed in deliberate attempts by policymakers in some jurisdictions to introduce tougher 'intermediate' community sanctions with the explicit aim of enhancing the legitimacy of alternatives to imprisonment (Tonry, 1996). In the UK, this has led to the rebranding of community service orders, for example, as 'community punishment orders.'

Punishment as Sentencing?

The above analysis treats as unproblematic the fact that punishment follows conviction and sentence and that the 'object' of punishment must be convicted in a criminal court. Of course, in practice such neat divisions are rarely adhered to as suggested by research on the variety of ways in which police can informally punish suspects (for example, through denial of 'station' bail) (see, for example, McConville and Hodgson, 1993). While technically the purpose of the earlier stages is not to punish but to determine guilt or innocence, the reality for the offender is much different. As first recognized by Malcolm Feeley in his book *The Process is the Punishment* (1979), the distinction between the pretrial and sentencing stages (attendant on formal adjudication) is largely illusory for the offender. From his/her vantage point, punishment in the form of arrest, detention, prolonged pretrial custody, etc., begins prior to formal adjudication and this is becoming increasingly significant as the difference between 'accused' person and 'offender' is incrementally blurred (Brown, 2008).

The objection to such a position is that these informal, and sometimes illegitimate, practices by police may be analogous to punishment but to describe them as such would be to endow them with a legitimacy, which they do not merit. This is, however, to privilege a formal or 'legal' view of punishment over the offender's perspective; to prefer the 'law in the books' to 'the law in action.' A proponent of the broader view is Lynch (1995: 27) who argues that sanctions can be administered at many points along the criminal process:

> Police officers can punish by taking you into custody or giving you a warning or a citation. The prosecutor's decision to prosecute or not can be construed as a form of punishment. Judges can punish at sentencing. Prison and parole officials can punish through classification, decisions regarding good time or early release, decisions regarding institutional discipline, and revocation decisions.

The point is particularly important when it comes to cross-national comparison. The paucity of data on decisions made earlier in the criminal justice process often leads to a concentration or focus on the sentencing decision and beyond. This results in cross-national studies of punishment policy in fact becoming comparisons of prison use (Young and Brown, 1993). In her work on punitiveness in Ireland, Scotland, and New Zealand, Hamilton (2014) developed and applied a multidimensional test for punitiveness, which incorporated aspects of the criminal process beyond the narrow focus on the sentencing stage. The surprising homogeneity suggested by the results suggests the utility of a broader test in order to capture the variability and complexity of punishment in contemporary penal systems. Similarly, expansive approaches to the cross-national measurement of punitive practices have also been suggested by Pease (1994), Whitman (2003), and Kutateladze (2009).

More formal legal mechanisms also provide for the imposition of 'penalties' on individuals who have not been convicted of a criminal offense but who have been brought before the courts for civil wrongs. These hybrid civil orders generally place liberty restrictions on their subjects that may be as burdensome as punishment but are not subject to the same sorts of protections of criminal procedure, for example, the criminal standard of proof. A well-known British example is the anti-social behavior order ('ASBO'), which can be made when a court is satisfied that the individual has acted in a manner 'likely to cause harassment, alarm, or distress to another' and which attracts a penalty of up to 5 years imprisonment if breached. The issue of whether ASBO proceedings are criminal, 'in reality and in substance' has been considered and rejected by the UK House of Lordsin *R (on the application of McCann) v. Manchester Crown Court* ((2003) 1 AC 787). Perhaps most significantly, however, for the purposes of the present discussion, the Law Lords held that ASBOs, unlike ordinary criminal penalties, are designed to *prevent* antisocial behavior rather than to *punish* the offender. Ashworth (1998, 2004) has questioned the approach of the English courts to the issue and has drawn attention to the robust case law developed by the European Court of Human Rights in this area. (See *Engel v Netherlands* (1976) 1 EHRR 647; *Welch v. UK* (1995) 20 EHRR 247.) The Court has held on several occasions that, in order to prevent subversion of the procedural safeguards guaranteed in the fair trial provisions of Article 6 of the Convention, the term 'charged with a criminal offense' should be given an autonomous meaning, which looks to the substance rather than the form. What is known as the 'antisubversion doctrine' exists to prevent states simply reclassifying criminal proceedings as civil in order to avoid the protections attaching to defendants in criminal proceedings. As Ashworth (2004) argues, this approach is preferable in that it allows consideration to be given to the (potentially far-reaching) impact and

consequences of the order for the 'offender,' as well as the purpose of the order as imputed by the state. This is an area, which is likely to be the focus of much debate into the future, given the rise of coercive measures pursued through civil or administrative channels. As will be further discussed, these are particularly prevalent in the counterterrorism sphere where threatened states have introduced measures incorporating forms of highly restrictive house arrest (e.g., control orders in the UK and Australia and Security Certificates in Canada).

Beyond the Penal State?

Thus far punishment has been discussed in the context of pain or hard treatment imposed by authorized agents of the criminal justice system. Extending conceptions of punishment beyond the criminal justice system may appear to blur the boundaries between punishment and broader mechanisms of social control, sometimes treated as the independent variables in any analysis. Low levels of imprisonment in Japan, for example, are often explained with reference to the high levels of informal social control and the risk of ostracism for rule-breaking (Nelken, 2010). Convincing arguments may be made, however, for the inclusion of broader regulatory mechanisms in examinations of punishment practices and in some cases, it is arguable that a satisfactory understanding of the harshness of states or communities at given points in their history cannot be achieved without such an expanded definition. A few examples serve to illustrate that it may be difficult to justify *not* taking account of these factors. In the United States, there were 15 times fewer black people in prison prior to the abolition of slavery than afterward (Melossi, 2002 cited in Nelken, 2006), yet it is difficult to claim that American society was really more lenient then. Further, in an Irish context, O'Sullivan and O'Donnell (2007, 2012) have convincingly argued that the reversal of previous levels of noncriminal incarceration such as asylums and Magdalene homes casts contemporary increases in imprisonment rates in a very different light, particularly for women and children. Using the alternative analytic framework of 'coercive confinement,' they chart not only the numbers detained in prisons and borstals but also the thousands of men, women, and children who were incarcerated in psychiatric hospitals, mother and baby homes, Magdalen homes, reformatory and industrial schools during the first 50 years of Irish independence in the middle years of the twentieth century. In demonstrating that incarceration rates were eight times higher in 1951 than 2002, they both locate the prison as part of a wider network of institutions or 'carceral archipelago,' which was integral to the early Irish state and serve to complicate current dystopian analyses of contemporary punishment in Ireland and elsewhere.

Narrow conceptions of punishment as sanction imposed for breaches of the criminal law are also highly challenged in light of coercive practices deployed by states in the recent 'war on terror.' Counterterrorism measures adopted since the events of 9/11 by countries such as the United States and UK rather evoke a 'coercive spectrum' with criminal law at one pole and a series of extralegal measures such as extraordinary rendition, torture, and military detention at the other. In the middle are a range of legal measures such as control orders (in the UK and Australia), civil forfeiture laws and immigration detention, all of which operate on the margins, or outside of, the framework of the criminal law. In an important analysis of recent sociolegal changes, Lazarus et al. (2013: 463) argue that "various domestic and international pressures have led to a significant shift away from the punishment model in the exercise of state coercion." For them, the emerging use of these preventative techniques raises serious questions about the extent to which we are witnessing a "displacement of legal punishment as the primary mode of delivery of state coercion" (2013: 484). The focus on 'security' and 'prepunishment' rather signifies a temporal shift within the field of coercion frequently justified in the name of exceptionalism than by more traditional notions of retributivism, deterrence, or rehabilitation (see also Zedner, 2007).

While the trend toward extralegal measures is perhaps most obvious in the United States (Baker, 2013), it has been argued by some scholars that European policies such as interception of communications, data retention, data profiling, and the introduction of the European Arrest Warrant represent more punitive measures, as measured by interference with the human rights of those involved (Hosein, 2005). Similarly, Baker (2010) speaks about the extent to which the European Union has exchanged 'governing through crime' for 'governing through security,' given its degree of investment in initiatives to strengthen security. Certainly, there has been a definite shift within the European Union in recent years toward the criminalization of immigration (Melossi, 2013). At a rhetorical level at least, Dumortier et al. (2012) observe a remarkable blurring of the boundaries between the immigration and criminal justice systems, as evidenced in European Union initiatives such as the Framework Decisions of 13 June 2012 concerning terrorism.

Analytic attention may also be brought to bear on the question of whether the 'authorized agents of the state' mentioned above refer strictly to 'state' or 'public' actors or whether this may also include certain nonstate bodies to which the state has delegated its power for certain purposes. While punishment may be regarded as an inherently public function, justification of the privatization or marketization of prisons, which has occurred to a significant degree in countries such as the United States, UK, and Australia has rested on the distinction between the *allocation* and *delivery* of punishment (Logan, 1990). Sparks (1994) takes issue with the sharp distinction drawn between these two functions, arguing that this arrangement "tends to sandpaper away the contested and 'dismaying' nature of state punishment" (Garland, 1990: 1). In other words, the managerialist tendency to treat punishment as a mere 'technical' matter capable of delivery by any agency to which the state delegates this function serves to divorce the debate from punishment's core characteristics, namely, the deliberate imposition of pain requiring the highest possible justification. It is also, as Zedner (2004) remarks, a highly artificial position, one which ignores the role of prison authorities in determining (through prison disciplinary proceedings and other discretionary mechanisms) the amount of punishment, as well as its delivery. Whether the delivery of pain by private agents should be described as 'punishment' poses similar questions to those raised above concerning punitive practices engaged in by the police, namely, whether

this serves in some way to legitimate their actions. As also discussed above, however, and given the extent of private involvement in contemporary punishment, an authentic approach to this issue should embrace a more expansive definition of punishment in order to reflect the reality of pain delivery for the offender.

Abstract

The most striking development in twentieth-century penal politics was the emergence in the advanced democracies of the state that punishes as few and as little as it can. Convergence on policies of minimal punishment, as measured by the ratio of prisoners to robberies, occurred in spite of high unemployment, growing ethnic diversity and conflict, a drugs pandemic, and an average of sevenfold increase in serious crime. Convergence on leniency was paradoxical – given democratic competition, constant crime coverage in the media, and the persisting, even growing, crime-induced popularity of punishment among voters. The paradox is perhaps explained by such factors as Elias' civilizing process, penal sentimentalism, secularization, the welfare state, professionalism, and persisting elite control.

The Minimally Punishing Democratic State: Can a Democracy Punish?

A not-much-noted yet striking development in twentieth-century penal politics was the emergence in the advanced democracies of the minimally punishing state. Convergence on policies of minimal punishment, as measured by the ratio of prisoners to robberies, occurred in spite of high unemployment, growing racial and ethnic diversity and conflict, a drugs pandemic, and an average sevenfold increase in serious crime. Convergence on leniency was paradoxical – given democratic competition and the persisting, even growing, crime-induced popularity of punishment among voters. And indeed, the minimally punishing democracy emerged during one of the largest crime waves in recorded history – a Great Crime Wave impressively absorbed and ignored by all democratic political systems for one or more decades (Figure 1).

Modern democracies were strong enough and morally neutralized enough to dismiss the demand for a state response proportionate to the crime wave – a wave reflected in the annually mounting numbers of thousands, even millions of crime reports. Most democratic governments displayed surprising capacities not to punish in spite of the victim's entitlement to punishment implied by their penal codes. (No penal code contains a warning label to citizens that the punishments it threatens will be applied at most to 3% of those arrested and 1% of those who violate its terms.) Attrition rates for criminal cases became extremely high in all democracies, from the apparently most punitive to the least. (It would be comforting if this severe attrition reduced punishment to only and all the worst offenders. But the criminal law is easily manipulated and its administration heavily affected by fortune and Fortuna.)

A conclusion seems to have been reached in most democracies that the state can get away with never needing to punish (or at least imprison) much more than 100 per 100 000 people at any time, no matter which or how many or against whom crimes are committed (Figures 2–6).

These historical graphs incidentally show no impact of the gradual democratization that took place in those countries between 1850 and 1950.

The Convergence on Minimal Punishment

Nonenforcement has been the usual case in all democracies, of whatever repute for punitiveness. The facts of convergence on minimal punishment levels are clear. In 1940, most of the currently advanced democracies had capital punishment; by 2000, only two of them still inflicted the death penalty and only on a much reduced scale. In 1960, in the advanced democracies on average 11 prisoners (for all offenses) per reported robbery; by 2010, the average democracy had one prisoner per robbery. Between 1960 and 2010, the democratic state largely relinquished (despite public opinion) the threat of death punishment and reduced to lottery-odds the likelihood of prison punishment (Figure 7).

What Caused the Historical Rarefaction of Punishment?

Theories of overpunishment abound, given the hostility of most academic theorists to putting lower class criminals in jail or prison, not to mention executing them for murder. Harder to find are theories of underpunishment, unless one deals with crimes of the rich and powerful, where "the rich get away with murder" is axiomatic. (In spite of the axiom, the rich and powerful also remain the succulent targets of the media and ambitious prosecutors.)

The State Monopoly of More or Less Legitimate Punishment

One of the integral elements in the formation of states was the state monopolization of legitimate drastic punishment. For centuries, feudal lords, towns, and counties proudly displayed gallows as the mark of their sovereignty. Once local control of gallows was surrendered, monopoly allowed the state to reduce and then eliminate capital punishment.

State Elites' Conversion to Leniency

The decision to ration punishment came to rest on what had become, by the 1960s, a gap between the lenient mentalities of

political elites and the more traditionally punitive, if sometimes also ambivalent, mentalities of the mass public. This gap was best explained by Norbert Elias, who traced what he called "the civilizing process" – the diffusion of antiviolence mentalities among and by the middle and upper classes since the Middle Ages (Elias, 2000). Elites in the Western democracies became remarkably comfortable with lower class violence especially since the targets of that crime were usually other lower class

victims. The police were invented in part to keep lower class crime targeted on other lower class people.

Penal Sentimentalism Rationalizes Elite Indifference to Lower Class Crime

The medieval elite – mass gap in penal sentimentalism widened with the further top-down spread of the ideas of the eighteenth-century Enlightenment and of the nineteenth-century Romantic, liberal, and socialist movements – humanitarianism, human perfectibility, and society's responsibility for crime. There arose an implicit understanding that civilized people do not believe in punishment. Criminals indirectly acquired great political influence: for many in the elite, they became objects to protect, not punish.

There was also a darker side to elite tolerance. Many people, especially intellectuals, were excited by the idea of violence, especially political violence or class warfare violence. The powerful appeals of Marxism (and Nazism) for Western intellectuals often rested on the legitimacy of violence for noble purposes. Sympathy for criminals as victims of capitalism rested (and rests) on elite contempt for capitalism.

Secularization and the Christianization of Penal (and Social) Policy

Surprisingly, Michelangelo's *Last Judgment*, in the Sistine Chapel, has not been painted over – not this time, of course, to cover nudity but to combat any possible notion of Christian, divine, or Church endorsement of hellish punishment. The *Last Judgment* survives even though it is judgmental. Since the eighteenth century, and in spite of the twentieth century, pessimism about human nature and the concept of original sin (although not in its Freudian reincarnation as universal, genetically innate aggression) have become outdated, reactionary, intolerable ideas.

Late in the nineteenth century, a new democracy emerged, the Nietzschean democracy where God is dead, Hell is only a bad dream, and paradise on earth is achievable. Crime is no longer immoral, but merely deviant behavior.

The private sector has taken up some of the slack created by the defaulting state: private policing and private punishment thrive. Much crime consists of acts of private, drive-by, Union Corse, and Godfather justice – never displaced by public justice.

Figure 5 Decline of punishment in the Australian states.

Juvenilization of Justice: Age Discrimination in Penal Codes

One of the great challenges any society faces is to domesticate ever oncoming cohorts of young males. Of all the groups in democratic societies, the most challenging to peace and order, life and limb, are not the proletariat or the poor, but emerging cohorts of young males. These are in any society the readiest by hormonal inheritance to seize opportunities to commit violence, riot, and massacre (Banfield, 1974). They are also the readiest to expose themselves to violence to defend society against the young men of other societies – the readiest to be heroes in war, as well as the readiest to be villains in peace.

In spite of biology, penal sentimentalism has found ready application to young males ('adolescents'), the young offenders (usually male) who have not been convinced by the age of 5 or 10 or 15 or 20 that hurting other people is wrong and not a legitimate source of pleasure. To be sure, growing up in rougher communities, it is safer to be known as violent.

The Minoritization of Crime

Given millennia of racism as a set of normal attitudes, it is surprising that in the twentieth century, the domination of much crime in the Western democracies by racial and alien minorities has had relatively little impact on punishment rates. Many places have kept low punishment rates by simply replacing domestic offenders with minority offenders. One of the reasons behind the Great Crime Wave is that in the 1960s for the first time, the violent crime in minority areas ('China-towns') began to be reported to and recorded by the police (Figures 8 and 9).

One might have thought, given 'tribal' prejudices against outsiders and feared minorities, that punishment rates would have soared. But, thanks to Hitler and his enormities, overt racism, rather than normal became abnormal, even detestable. Capital punishment in the United States almost disappeared and reappeared only on a minor scale – even though half the murders involve blacks (only 12% of the population).

Welfare State Clientelism

The welfare state discredits the very notion of punishment because the welfare state was founded to reduce, not to increase suffering. Even today, there is a seldom-questioned belief that criminal impulses will be eliminated by a big enough welfare state. Thus, the welfare state as built in Sweden (having

Figure 6 Decline of punishment since 1880.

eliminated need and greed) should have had little or no crime. Figure 10 shows that crime has more than thrived in the beacon welfare state. *Au contraire*, the welfare state has sharply reduced the negative consequences of doing crime.

The welfare state is designed to eliminate the unpleasant consequences of any kind of personal 'misconduct': crime, heavy drinking, casually impregnating women, spreading a social disease, dropping out from school, beating one's wife and kids, mugging someone on the street, and taking drugs. No one is to be 'marginalized' in the secular version of a Christian community. Thus, in German politics, it is still common and not silly for politicians to quote an aphorism of the progressive penal theorist von Liszt (1851–1919): Sozialpolitik ist die beste Kriminalpolitik. "Social policy is the best anti-crime policy."

The proper welfare state will also produce full employment and this, in the minds of many people, will prevent crime. It is received wisdom (no matter how often challenged by negative correlations between crime and unemployment) that unemployment means crime. For example, unemployment in the United States rose from 4% in mid-2008 to 10% in 2009 and 2010, dropping to 8% in 2012. The violent crime rate dropped from 458 in 2008 to 404 in 2010 and the property crime rate dropped from 3214 to 2941 (Figure 11).

Capitalism

Persisting neo-Marxists, seeing class economics always as *primum mobile* (the 'root' cause, cause of causes) have returned to the idea that capitalism (now in the guise of neoliberalism) fosters (needs?) increased imprisonment (Nelken, 2009). They argued that at least some types of capitalist systems (neoliberal ones) are exclusivist, with prison just one form of social exclusion. Imprisonment, rather than crime-related, results from neoliberal propensity to exclude undesirables. Other capitalist systems (such as in Europe) prefer to include (keep?) criminals around in society. This is perhaps why the leading neoliberal system (the United States) has come to have many lower crime rates than the inclusive (social democratic) capitalist systems. Strangely, neoliberal systems like England, the United States, and Switzerland have radically different per-capita prison populations: in 2010, 79 (Switzerland), 153 (England), and 756 (the United States).

Prisons and Budgets: Prisons versus Payouts

In democracies, government programs compete for shares in the budget. In the West, when budgets are made by government leaders alone, prisons often fare badly. Justice ministers are rarely powerful members of the cabinet. When prison-building bonds are put to the public for a vote, they fare better. Generally, however, welfare programs have much greater budget appeal than prisons: they involve tangible, spendable individual benefits and produce powerful interest groups to defend and expand their benefits. There are also greater payoffs (metaphorically speaking) for spending on policing than on prisons. Policing is an at-hand benefit compared to prisons. Moreover, governments have found that solving a few scandalous crimes and demonstrating government control of the streets may obviate the need for large numbers of routine arrests and prosecutions.

The drive to separate punishment policy from crime policy is often mirrored in the creation of separate ministries for crime (Interior) and punishment (Justice) – headed by ministers

Figure 7 Convergence on minimal punishment.

known for being 'tough on crime' (Interior) and *laxiste* 'soft on crime' (Justice). To separate punishment from crime is the triumph of the antipunishment movement. Whence the regular complaint: "Interior catches, Justice releases."

Utilitarian Considerations: Prisons Fail versus Prison Works

Since at least the eighteenth century, prison reformers have tried to convince themselves and government that prisons are not (or should not be) punishment institutions but treatment or 'correctional' institutions. But as the belief in correctional benefits of prison has gradually faded, some social reformers have lost enthusiasm and joined the antiprison crusade. Belief in rehabilitative prisons, however, still survives in the twenty-first century. Tory Minister of Justice Clarke announced in 2011 that prisons were not (as he had somehow after all these years thought) rehabilitative and therefore should be emptied. Clarke's decarceration plan was opposed even by Labour leaders and most of the Tory Party.

Antiprison Professionals and Experts: Professionalism as Power

Foucault was all too right about the importance of professionals in modern life. Professionals want punishment policy to be a private preserve free from 'punitive populism' or populism of any kind; 'elite antipunitiveness' is to be like most government policies, almost totally invisible. Professionals

Figure 8 Minorities in prison *c.* 2000.

have been successful in Europe in separating punishment from crime because of the strong European acceptance of what the Swedes call (and routinely accept) *styrning uppifrån* (governing from above).

Alfred Blumstein, one of America's most eminent penalists, has even written that "one's normal conception of punitiveness [as measured for example by prison rate] [is] inconsistent with the principles of democracy" (Blumstein, 2007). Professionals have invented a set of insults to apply to any negative public response to crime and criminals: 'moral panic,' for example, suggests that crime fear (rather than based on burglaries and muggings in the neighborhood) is only fear of the bogeyman.

Opposition to prison (except as alternative to the death penalty) became in the nineteenth and twentieth centuries the mark of an enlightened, educated person and a prerequisite to standing in the helping professions. Expert opinion matters politically because governments often seek to legitimize action as being based on the best advice of the best professional experts. Given the domination of antipunishment attitudes

Figure 9 Minorities in prison.

among the experts, whether lawyers, sociologists, penologists, correctional officials, justice ministry bureaucrats, psychiatrists, journalists, clerics, or social workers, the separation of prison and crime and indulgent advice emerges routinely (e.g., Downes, 1992).

Finland is much feted for reducing its prison population by more than two-thirds since 1950 (despite the rise in the number of robberies from 210 in 1950 to 2600 in 2000); not incidentally does its leading penal expert describe the penal policy process in that country as "exceptionally expert-orientated. Reforms have been prepared and conducted by a relatively small group of experts…The impact of these professionals was further reinforced by close personal and professional contacts between some politicians, state officials and academic researchers. Consequently…crime control has never been a central political issue in election campaigns" (Lappi-Seppälä, 2002).

Typifying the bias of almost all penal experts has been the standard use of per-capita denominators in measuring prison rates and 'punitiveness.' Overpunishment is almost universally defined as anything above 100 prisoners per 100 000. The crime rate is bizarrely considered an irrelevant denominator by most experts in determining desirable punishment levels. The prisoners-per-capita rate, moreover, is not only easy to calculate but has great utility in the fight against imprisonment: comparisons are so easy and they all show how prison rates can be held low in such respectable countries as Sweden and

Figure 10 Crime prevention in the Swedish welfare state.

Switzerland – only the will to take expert advice and make imprisonment rare is necessary (Figures 12 and 13).

The author uses instead a nonconformist ratio: prisoners per robbery. Robbery has the advantage of being a serious crime, not that rare, that has for decades been recorded by most jurisdictions. Using the prisoner-per-robbery ratio produces radically different rankings in punitiveness and has the logic of relating punishment levels to serious crime rather than, say, the price of cabbage.

Eminent experts also argue that if crime has gone down in country A, which has raised imprisonment rates (say the United States), but also gone down in country B that did not raise imprisonment rates (say Canada), the raising of imprisonment rates cannot have been the cause of the drop in US crime. For some undisclosed scientific reason, every result must have the same cause everywhere.

Major comparative works have been published by professionals in the 2000s. An impressive number were sponsored and written by Professor Michael Tonry. Tonry's rich and detailed work represents the antipunishment movement at its most sophisticated. It is, of course, unashamedly antidemocratic, castigating 'politicization' and 'polemicization' when delicate questions of penal policy are involved. Election campaigns involving justice issues are debased by 'emotive appeals' resulting in 'coarse' policies (Tonry, 2007).

Hitler-Tainted (but Not Stalin-Tainted) Penal Policy

Hitler's glorification of law and order discredited the very notion of law and order. Punishment as a normal sequel to crime became tainted as fascistic. In the democracies, the antifascist parties after World War II (after inflicting sometimes indiscriminate punishments on collaborators) found punishment legitimate only as 'treatment.' One lesson of the Hitler experience was not learned: penal laxity breeds political extremism. The extreme right-wing parties to emerge in the later twentieth-century Europe often derived from the need for some party in France, the Netherlands, Italy, Norway, and Sweden to express popular feelings about the Great Crime Wave.

The Defendant-Rights State

Procedurally, the ideal democracy remains the Blackstonian state, which proudly releases 10, 20, even 100 guilty if necessary to acquit one innocent (Volokh, 1997). The Blackstonian state found its apotheosis in the US Supreme Court Miranda-

Figure 11 Unemployment rates vs prison rates.

type decisions of the 1960s and 1970s designed to make conviction and punishment as difficult as possible – this during the worst crime wave in American history. In the 1960s, the accusing state was presumed guilty.

Paradoxically, the more a country's justice system resembles the 'crime control' model rather than the 'due process' model (Packer, 1964), the more lenient its penal practices may be. Dutch criminal process is perhaps the least due process system among the advanced democracies; but criminals are totally willing to confess their crimes, knowing that the penalty will be slight. Criminals need no Blackstone when penalties are penalties-lite.

Cultural Consistency

Criminal justice in modern democracies is not unique. The decline of punishment is not restricted to the handling of criminals; it occurs in all spheres of society: the family, schools, the military, the university, jails and prisons, unionized business firms. A nonspanking family corresponds to a non-punishing state. To be legitimate, punishments have to be called something else and to be mild, painless, judicially supervised, easily obstructed by lawyers, and drowned in documentation.

The Great Crime Wave: The Role of Criminals (Deviant Individuals) in Reducing Punishment Rates

The prisoner-per-robbery ratio sank low after World War II because of the surge in robberies and a slump in prison sentencing. Figure 1 shows the dramatic success (numbers and productivity) of robbers in the democracies since 1960 (at least those reported). The democracies for some decades remained almost penalty-free paradises for robbers. Once-safe democracies after the 1950s were betrayed by their governments into allowing criminal activity to become normal. For example, violent crime increased by a factor of seven in Denmark and a factor of nine in the burgeoning welfare state, Sweden (Balvig, 2009). Reported robberies in Sweden rose from 190 in 1950 to 9570 in 2009. By the Nietzschean morality of the experts, tolerance for the Crime Wave made the Netherlands a beacon state 'beyond good and evil.' The average sentence for rape in the Netherlands was and is 11–12 months.

Figure 12 Per robbery prison rates *c.* 2000.

The Successful Challenge of Criminals to Mediocre Criminal Justice Systems

The 1950s were an idyllically safe period for most people – including those in minority neighborhoods. In the 1960s, however, thousands, indeed millions, of mostly young men rightly sensed a weakness in the authorities and stole, robbed, raped, and murdered – with impunity. And eminent jurists seemed oblivious in their rulings to any possibility that they might be encouraging the surge in rapes, aggravated assaults, and murders.

Overwhelmed by the mass of new candidates for punishment, the disjointed 'chain' of public authorities paid to deal

Figure 13 Per-capita prison rates *c.* 2000.

with criminals was able (with little criticism) to solve few crimes, prosecute (with little criticism) few of the few delivered into their hands, negotiate (with little criticism) convictions for only a few – on the basis of reduced charges. But the workload of judges was kept manageable. Prison sentences became rare but seldom served, and prison rates were kept respectably low (Figures 14–16).

What counted for the institutional survival and maintenance of these underpowered justice systems was the ability of the police, prosecutors, and judges to achieve occasional success in dealing with media cases. (Ironically, the institutional apparatus did play an important part in making the public aware of the seriousness of the crime problem – simply by repeating annual demands for more funds, personnel, and power to cope with 'an increasing crime problem.' This reinforced the conclusions from daily experience.)

The Netherlands, seemingly proud to tolerate crimes against its citizens, had no rivals when it came to refusing to acknowledge the Great Crime Wave. In 1980, the Netherlands, despite having a soaring crime rate, had the same small number of prison cells it had in 1840 when the country had one-fifth of the population.

Internationalization of Punishment Rules and Norms: Using the Treaty Power against the Voters

Prison reform, as well as the crusade against the death penalty and torture, have been international since Beccaria's *Dei Delitti*

Figure 14 Getting away with crime.

e dei Peni (1764). In the subsequent Age of Democracy, internationalization became a major way elites could escape democratic control over crime and punishment policy. Penal experts much prefer international definitions of rights, crimes, and punishments – definitions made by fellow experts (seldom by elected representatives) in far-off places, selected by national executive elites. Thus, adoption into domestic law of the European Human Rights Convention by Britain allows judges (picked far from any public's scrutiny) to overrule any English or Scottish judicial decision seen as violating a 'human right'

Figure 15 The gap between serious crimes and sentencing.

in the eyes of, say, an Armenian, Croatian, Montenegrin, or Russian justice.

Swiss elites, normally extravagantly concerned with national autonomy (they still refuse to join the European Union and joined the United Nations (UN) only in 2002), were happy to commit to the International Criminal Court, sign the European Convention on Human Rights, and accept the jurisdiction of the European Court of Human Rights – all means to remove justice questions from referendum voting. Adoption of that charter by the Swiss Parliament allowed European judges to overrule the usually sacred *vox populi* – a strong national referendum in 2004 in favor of life imprisonment for "sexual and violent criminals judged very dangerous and not criminal."

The mythology of internationalism is powerful – that international officials, bodies, courts, etc., are by some cloudy process made more objective, humanistic, and rights, committed than mere elected national authorities. In reality, the UN Human Rights Commission has routinely included representatives from states without human rights. Perhaps as important as formal international pressures against punishment are informal and regional pressures, such as those exerted on Finland by other Nordic nations. Finland maintained typically high Eastern European prison rates until the demise of

Figure 16 Comparative prison capacity.

its unofficial Big Brother, the Union of Soviet Socialist Republics. Then, in a dramatic effort to demonstrate its (west) European character, Finnish experts were able with no interference from Russia, Finnish party leaders, or Finnish voters to reduce its prison population to the lowest rate in northern Europe. Finland has thus made itself a 'beacon state' – a state that punishes criminals the least.

European countries like Finland want not only to be a beacon state but to be echt European (positive tropism), and not like the United States (negative tropism). Negative tropism toward the United States is one of the driving forces in European and Canadian government and politics, including penology.

Pretrial Detentions as Punishment

In a large number of democracies – national and local – pretrial detention serves informally as the principal 'dose' of punishment. Jails primarily house those who will never go to trial or if convicted, will be sentenced to 'time served.' Pretrial detention (deserved or not) is punitive but legally not punishment, at least in name, although conditions may be much worse than in convict prison. This is a major way in which police and prosecutors try to impose some punishment (Figure 17). (The population in pretrial status is, however, included in per-capita and per-robbery prison populations.)

Invention of Alternatives to Death and Prison: 'Net Widening'

Reformers have been fertile in creating ways for judges to avoid prison and death sentences via 'alternative punishments.' The death penalty has been replaced by imprisonment for life, life without parole, but most often, a dozen years or so in prison. Now also common in the United States is a 15-year delay between death sentence and execution. Generally speaking, taking a human life has been devalued, from being worth "a life for a life" to a dozen years in prison with color television and internet access. Incarceration as traditionally threatened by penal codes has been replaced by cautions, pretrial detention, deportation, probation, local imprisonment, part-of-the-week and part-of-the-day imprisonment, home arrest, restitution, community service, and shaking hands with the victim. But one must not forget queuing up for prison spaces: "we'll call when there is an opening for you." The Netherlands went in for prison waiting lists in a big way but eventually

Figure 17 Comparative detention rates.

doubled their minuscule prison capacity after a man accused of rape was put on a waiting list and then made the mistake of raping a journalist.

Ironically, the concept of 'net widening' was developed by professionals just when the net of justice caught few and punished fewer. Normally pro-state when welfare and business regulation was involved, professionals were antistate when crime or mental illness was involved. Prisons reached their lowest populations in the United States in the midst of the Great Crime Wave and, not coincidentally, at the same time that 'deinstitutionalization' began delivering thousands of formerly hospitalized mental patients onto the streets. Mental patients have come to form a growing percentage of prison populations.

Process Can Be Made Costlier: Fiscalism

Capital punishment has been made prohibitively expensive in most places in the United States. In order to boost the cost of capital trials and appeals to millions of dollars, lawyers and judges have been allowed to require the employment of expensive lawyers and experts in any capital trial before it can be considered 'due process.' With the rulings of two sets of appellate judges, state and federal, prisons in the United

States can be made costly to operate, difficult to manage, racially explosive, and unsafe. American judges routinely decide whether any particular set of prison conditions constitutes 'cruel and unusual' punishment. (Ironically, California was criticized for spending more money on prisons than universities, as if prisons might not make greater immediate improvements of life quality for more people than universities.) European prison systems, for their part, are bombarded with criticism from domestic and international bodies, sometimes because prisons truly look like hotels, more often because they can easily seem to be what American judges would consider 'cruel and unusual' punishment.

Prisons Showed How They Could Be Made Ungovernable

In 1971, riots and violent state suppression made 'supermax' prison Attica a symbol of state sadism or prisoner sadism, perhaps both. In the rebellious atmosphere of the 1960s and 1970s, supposedly isolated prisoners demonstrated their ability to become sympathetic actors on the international stage, challenging the right of governments to govern them, much less punish them. Prison ungovernability came from the weakening of elite confidence in its right to govern and punish. It also came from the extension of outside revolts against authority and racial/ethnic tensions into prison. Guards with uncertain authority in Europe and America are now supposed to govern prisoners of diverse language, nationality, race, religion, urban versus rural origin, status in prison and society, not to mention reputation for brutality and gang connection.

The Defeat of Democracy: Elite Control of Crime and Punishment Policy by 'Platonic Guardians' (Loader, 2006)

Democracy is a very inefficient system of punishing politicians. The great mass of people, untrained in graduate schools and not having a candidate for felony punishment in the family, might be expected to punish lax governments, judges, and prosecutors when they can. But there are powerful elite barriers to taking penal codes seriously or to responding to 'punitive populism' (i.e., kindergarten notions that you will be punished if you hurt other people). In most elections, there are too many issues besides crime at stake. A party that is tender toward criminals is likely also to be generous in welfare state benefits. Decades of social democratic leniency toward criminals were decades in which half or more of the voting population became dependent on government jobs, contracts, medical care, housing, and money.

Then, too, law and order rhetoric by parties and media and interest groups often serves to mask lenient prosecution and sentencing. The Thatcher period was 'full of sound and fury,' unrelated to continuing lenient imprisonment policies (Farrall and Hay, 2010). Even when politics seems to be dominated by law and order rhetoric, this often has little impact on police, prosecutor, court, and executive-release preferences and routines.

Savelsberg describes Germany's version of 'not too much democracy' as compared to America's version of 'too much democracy' as follows:

> [German politicians are] much less likely to be responsive [than American politicians] … Their re-election as legislators depends little on their responsiveness to public sentiments…And judges and prosecutors never face elections but bureaucratically managed
>
> promotion systems. … New interest coalitions are hard to forge, new ideas are slow to spread, and decision-makers are slow to respond … We should not be surprised by the great stability of the macro-outcomes of decision-making in Germany, or by the great stability in incarceration rates (Savelsberg, 1999).

Democratic societies, if criminal justice is any indicator, survive by performing at 5–10% performance levels. Democracies seem to handle the crime and punishment problem mostly by relying on class structure and social geography: quarantining violence, focusing police attention and jail sentences on ghettoes and *banlieues*, and policing ghetto borders.

The Occasional Defeats of the Platonic Guardians of Minimal Punishment

Voters, even in west Europe, do not always supinely accept the nonpunishment of serious criminals – often revealed only in media reports on the past judicial handling of those arrested or convicted of serious crimes. There are occasional revolts against elite high-mindedness and apathy.

The Netherlands

Even the much-lauded deferential Dutch voters eventually learned that they could disobey their subcultural masters and vote to express displeasure with rampant criminality. Their Catholic and Liberal masters, joined in the 1980s even by their Socialist masters, grudgingly began to acknowledge the horrendous crime problem and for the first time in a century to build some prisons. Holland in the 1950s had been one of the safest places in the world; it has since become, with the help of antipunishment prosecutors and judges, one of the safest places in the world to do crime.

It was and is very difficult for Dutch voters to affect national policy: they have no individual district representatives in parliament; their mayors and governors are appointed by The Hague; the party system is so fragmented that governing coalitions emerge only months after elections, often in no relation to the vote; and judges are all civil servants. But Dutch voters did, as noted, get some prisons built after two or three decades of suffering rising violent crime. In 2012, the government even began shutting some of them down in view of declining crime. But at the acme of its apparent punitiveness, the Netherlands, as **Figure 13** shows, still ranked in the bottom 1–2% of jurisdictions in the ratio of prisoners to robberies.

The Blair Revolution

After four consecutive defeats at the polls (1979, 1983, 1987, and 1992), the British Labour party chose Tony Blair as Shadow Home Secretary in 1992, and he shockingly declared that crime

was a socialist issue. Ironically, the Tories under Margaret Thatcher, the supposed Iron Lady, had appointed a long series of lenient Home Secretaries (Farrall and Hay, 2010). To satisfy Labour's traditionalists, Blair's slogan, which helped win the 1997 elections, was: "Tough on crime, but also tough on the causes of crime." The number of prison sentences did increase after Labour took over in 1997. (The Tories, in response to Blair's radically new stand, appointed their first tough Home Secretary, Michael Howard, in 1993.)

The US Penal Revolutions

When democracy is not artfully stifled, there is likely to be more punishment for more crime. Some American states carried out great reversals of penal policy. The lenient policies of the 1960s and early 1970s – including abolitions of capital punishment and reductions in prison populations – were rejected in state after state, beginning in the later 1970s. Ordinary Americans, unlike ordinary Europeans, can sometimes shape penal policy. California voters by direct democracy brought back the death penalty a year after its supreme court abolished it. A decade later, in retention elections, they removed supreme court justices who had found a reason to reject every one of the hundreds of death penalty case submitted to them. In other states, lenient prosecutors and judges were removed from office. Judges were encouraged to take crime seriously and incarcerations increased at the state and federal levels. But, as Figure 12 shows, punishment rates still vary greatly among the American states: states with big cities remain the least punitive.

The White March in Belgium in 1996

In 1996, hundreds of thousands of Belgians, although divided and subdivided by culture, language, religion, region, gender, and class, gathered together to protest the years of mishandling of pedophile cases by what passes for a state in Belgium with a march in Brussels. Although not a riot, the march achieved a reorganization of Belgian justice and the sentencing of the multiple child rapist/murderer to a 'life' sentence – 8 years after the first rape-murder.

Conclusion

Most often, however, democracy allows criminals (the few), allied with lenient elites ('Platonic guardians'), to outweigh their victims (the many). In perhaps most instances, punishment decisions in democracies (even in the direct democracies like the Swiss cantons and California) are made by focused and interested elites. (The nonpunishment of white collar crime, financial crime, political corruption, fraud, tax evasion, and multiple others may seem less outrageous than nonpunishment of violent crimes. But some of these crimes cause lots of direct hurt to people. Comparative study of democracies and their nonpunishment of bourgeois crime, however, is another, and probably equally dismaying study.)

Bibliography

The sources of the statistics in the charts come from mostly printed but scattered materials consulted in the libraries of UCLA, Yale, LSE, Institute of Criminology (Cambridge), Swiss Federal Statistical Office, British Home Office, Dutch Ministry of the Interior, Max Planck Institute (Freiburg), and more. Of primary importance were the sometimes long runs of prison statistics contained in the statistical yearbooks of nearly twenty countries and about 80 sub-national states in those countries. Current statistics are available also in the Council of Europe, Annual Penal Statistics. Invaluable is the European Sourcebook of Crime and Criminal Justice Statistics. Several volumes of the Criminal Justice annual published by the University of Chicago Press have been devoted to comparative penal politics.

Punishment: Social and Legal Aspects

Abstract

While punitive sentiments come as close as any human motivations to being universally observed, the major finding from the history of punishment is one of change and variation. The scholarly study of punishment as social and humanistic inquiry has sought to make sense of the major shifts in punishment and society through historical and comparative research drawing on insights and inquiries from five theoretical 'toolkits.'

Punishment, Law, and Society

> the concept of 'punishment' presents, at a very late stage of culture … not just one meaning but a whole synthesis of 'meanings.'
>
> Nietzsche, 1994: p. 57

Research from fields as diverse as psychology (Vidmar and Miller, 1980), evolutionary biology (Gachter et al., 2008), and archeology (Gager, 2006) suggests that the perceived/internal imperative to punish, the sense of satisfaction at the thought of a wrongdoer receiving some compensating sanction, is a cross-cultural universal found in virtually every society of which we have records. It is arguably rooted in the evolutionary advantages achieved by primitive human groups who practiced it. But while the imperative to punish may be a general human trait, the historical record suggests that the methods, the meanings, the motivations, the justifications, the organization, and the myriad effects of punishment vary enormously and change over time according to a wide variety of social, economic, political, legal, and cultural factors (Durkheim, 1969; Rusche and Kirchheimer, 1939, 2003; Garland, 1990; O'Malley, 1999; Hudson, 1996).

It is the whole 'penal field' (Page, 2013), defined by those means, meanings, and consequences, and the dynamics of change within it, that forms our subject. A generation ago, it would have been subsumed in the field of penology, the scientific study of criminal deviance and methods, for its diagnosis and reform. The history of previous penal logics or methods would be little more than a prolegomenon to the progressive march of experimentation. Today, for reasons suggested later, the historical change in this field has become and remains central. We can use the term 'penality' (Garland and Young, 1983; Garland, 1990) to describe this complex of techniques, institutions, discourses, and their historical genealogy. This article introduces the major historical transition points in Western penality since the early modern period and to the most significant 'toolkits' that have been deployed by punishment, law, and society scholars since the revival of the field in the early 1970s.

Part I. The Historical Context of Western Penal Development: Capitalism and the Nation-State

The contemporary penal landscape in the world today is largely the result of five transformational ruptures in Western penality since the early modern period.

Rupture One: The Festival of Cruelty

The rise of the nation-state beginning in Europe in the sixteenth century co-opted the traditional role of families and private local landholders in administering punishments, making public punishments and important theater for the display and affirmation of political authority (Spierenburg, 1984; Foucault, 1977). This seems to have gone along with an overall increase in the frequency and severity of punishment, especially the use of tortuous capital punishment as well as a gradual legalization of punishment (increasing levels of due process and the involvement of professional lawyers) beginning in the mid-eighteenth century (Langbein, 1994).

Capital punishment played a quantitatively small role in early modern penality, but its rituals played a central role in the system of state trial and punishment. In England, for example, black-hooded judges pronounced sentence in capital trials, followed by public performance of a vividly violent execution to eventual display of the corpse (Gattrell, 1994). In a typical European ritual, the performance of various forms of minor humiliation or painful treatment would precede the execution of capital punishment as the final event (Spierenburg, 2004). As the culmination of a 'festival of cruelty,' the execution emphasized physical suffering and its display (Foucault, 1977; Garland, 1990: p. 64).

Rupture Two: The Birth of the Prison

Beginning in the late eighteenth century, the states with the most advanced central administrative capacity began to reduce their reliance on capital punishment, especially torture-laden public execution spectacles, in favor of a range of less visible and sanguinary practices, including transportation, public labor, and carceral confinement. By the middle of the nineteenth century, the scaffold as the main event in public capital punishment largely disappeared within the walls of a form of

punishment that had become the most successful alternative to replace it, the prison.

Rupture Three: Surveillance Societies

Beginning in the late nineteenth century, and through the mid-twentieth century the most advanced states professionalized and extended their penal system from prisons to community surveillance. Specialized carceral regimes for juveniles and other classes of offenders emerged (Garland, 1985; Rothman, 1980). The focus of prison regimes on discipline and hard labor also shifted in favor of education and training. A new set of penal practices, including parole, probation, and juvenile justice, saw modern state penal control extend from the prison into the community. Historians have treated this as a considerable expansion of state power over the poor and working classes. Using the metaphor of a net, these new penal forms are said to have widened the extent of the net (extending social control to more citizens) and thinning its mesh (closing the gaps through which lower-level offenders previously escaped sanction; see Platt, 1972; Rothman, 1980; Cohen, 1985; Rubin, 2012).

A new penological discourse combined the promise of rehabilitation through psychological and educational interventions, with eugenic prevention through incapacitation. It promised to reform the nearly century-old penitentiary project and create new forms of community supervision. The 'new penology' as it was sometimes called, promoted the ideal of individualized treatment, normalization (that is, preparation for return to the community), and progressivity but only for those deemed biologically suitable for success in free society. The strong influence of Darwinian population eugenics and scientific racism informed penal policy even more profoundly. The result was a broad extension of a penal field that remained heavily oriented toward imprisonment in non-therapeutic penitentiaries designed to incapacitate large numbers along with the most basic and externally unpromising forms of labor (Rothman, 1980; McLennan, 2008). World War II and global revulsion at the crimes of the Axis regimes helped to discredit the eugenic aspects of this approach, while its rehabilitative and correctional features became inscribed in central human rights charters. They were also embraced by the penal laws in most parts of the world, albeit with widely varying degrees of actual compliance, by the middle of the twentieth century. Following the war, penal systems in the wealthy democracies slowly moved toward a greater realization of the therapeutic model of reform penology, one bolstered in part by the rising wave of human rights thinking (International Covenant of Civil and Political Rights, Art. 10.3).

Rupture Four: Mass Incarceration

In the late twentieth century, the United States experienced a rapid and dramatic rise in numbers of people incarcerated in jails or prisons, and under community supervision, along with a qualitative shift toward harsher and more degrading punishments (Garland, 2001; Gottschalk, 2006; Western, 2006; Wacquant, 2009; Lynch, 2010; Whitman, 2003). This has been experienced by minority populations in particular, who saw already high mid-twentieth century levels of imprisonment reach supersaturation rates (Davis, 2003; Western and Petit, 2004; Alexander, 2013). A similar, but less dramatic growth in the scale of penal populations has occurred in other parts of the Anglozone, Europe, as well as parts of Latin America and Asia, mostly with a lag of a decade or more (Lacey, 2013; Pratt, 2007; Nelken, 2011) although nowhere near the levels of the US. As with racial minorities in the US, immigrants, especially those from outside Europe with marginal legal status have been a major focus of increased imprisonment in these nations (De Giorgi, 2006).

In the United States, the increase in prisoners has been fueled by a populist politics of punishment and the abandonment of modern correctional objectives and restraints (Scheingold, 1991; Garland, 2001; Simon, 2007). The modernist correctional apparatus associated with twentieth-century penology has been transformed from a normalizing force of social control, on both society and the penal system, into a managerial expertise with little knowledge of crime and little commitment to humane treatment (Feeley and Simon, 1992; Bottom, 1995; Garland, 2001). Rehabilitation and selective incapacitation of the incorrigible as modernist penal rationales became discredited from a variety of scientific and political perspectives, and a more generalized logic of incapacitation – anchored in a perception of prisoners as representing a high, unspecified, and unchanging criminal risk (Zimring and Hawkins, 1995; Simon, 2014) – took over.

Rupture Five: Dignity

There is evidence of a fifth rupture in process today in the emergence of globalization and institutions of international legality, and framed around the problem of human rights. Since the adoption of the UN Universal Declaration of Human Rights in 1948, considerations of human dignity and protection from torture, cruelty, and degradation have gradually become more central to legal challenges to penal practices and policies. In some countries and whole regions, human rights norms are reshaping the penal field through legal constraints on severe punishments as well as normative pressure on penal institutions to shape routines that conserve the dignity of those being punished and those carrying out the punishments (Whitman, 2003; Van Zyl Smit and Snacken, 2009).

This represents a major shift away from the idea of punishment as a form of state policy aimed at managing and securing the population. Whether in the form of the interventionist treatment-oriented penal welfare state of the mid-twentieth century, or the punitive and incapacitation-oriented penal state of the late twentieth century and early twenty-first century, modern punishment has presumed a strong state utilizing punishment to defend society (or critiqued for using it as a political tool). Human rights norms were largely relegated to the periphery, in the gradual abandonment of certain severe penalties as inhumane (torture, mutilation, slavery, solitary confinement). In the robust version now operating in Europe, the entire course of imprisonment is subject to three key demands necessary to preserving the human dignity of prisoners: (1) individualization, that is, decisions about them must be made with consideration of their individual circumstances and how that may change; (2) normalization, as much as is feasible, prison life should harmonize with free life and prepare

prisoners for return to freedom no matter what their actual prospects for release; and (3) progressivity: the possibility of change and improvement in the prospects of prisoners as their sentence is served (e.g., presuming good behavior) no matter what their actual terms of release. Citing the dignity principle, a number of globally influential human rights courts found unlawful the issuance of life sentences (known as 'life sentence without parole' or 'LWOP' in the United States) (Vintner et al. vs the United Kingdom, 2013).

Part II. Punishment and Social Theory: A Toolkit for Exploring Penal Variation and Change

The question of how these ruptures in penality relate to particular changes in law and society has produced an extensive and growing body of both social theory and empirical study. This literature is far too extensive for a handbook (Simon and Sparks, 2013) let alone an encyclopedia article to begin to summarize, but following the productive model of Garland's (1990) *Punishment and Modern Society*, I describe five major 'toolkits' drawn from both classical and contemporary social and cultural theory, being used in sum or in part by many scholars, to describe and explain changes in punishment, law, and society.

Toolkit One: Punishment and Solidarity

For Durkheim (1964, 1969) crimes are any action that violate or offend the fundamental moral values, or collective conscience, of society. When members of society come together to punish the crime, their moral outrage reassures the people of their collective commitment to these shared values, thereby reinforcing society's solidarity. Punishment thus helps to hold society together and provides its normative structure.

To Durkheim, these visible changes in penal practice were an empirical reflection of underlying changes in the social solidarity of modern societies. Traditional societies, characterized by little division of labor or variation in social forms, and unified by powerful, demanding, and often sacred norms in what Durkheim called 'mechanical solidarity' (a strong form of mutual identification through likeness), produced harsh punishments that reflected the large role played by the penal law in reproducing such solidarity. Modern societies, characterized by an extensive division of labor, diverse social forms, and unified by shallower but more extended norms associated with rational and secular values, produced more lenient punishments that reflected the reduced role of penal law in reproducing solidarity (the greater burden of which was now carried by what Durkheim called 'restitutive law,' including the law of contracts).

In a later elaboration (1903) Durkheim largely credited the reduction in traditional religious values for reduction in both the qualitative demands of punishment (whether it demands permanent mutilation or death on one hand or 'merely' a term of penal service on the other) and the overall severity of its output (whether the number and severity of sentences goes up). In addition to these long developmental processes, Durkheim recognized the significance of shorter term political developments, such as the potential for authoritarian governments to use punishment to inspire popular fear and awe among the masses.

Durkheim was reflecting on ruptures one and two. Since the rebirth of interest in punishment and society in the 1970s, scholars have drawn on aspects of his account to explain the emergence of penal welfarism in the twentieth century (rupture three; Rothman, 1980; Garland, 1985). If human rights norms like dignity succeed in restraining mass incarceration and realigning global practices toward restraint and leniency, it will no doubt fuel Durkheimian theories of the emerging global society.

Toolkit II: Punishment and Social Structure

Marxist scholars have related penal change to the class structures of society, and particularly the changes associated with the rise of capitalism. Georg Rusche and Otto Kirchheimer (1939, 2003) explored ruptures one, two, and the beginnings of three as a function of the political economic conditions and the structure of class power underlying punishment and society. The harsh punishments of physical mutilation and death frequently exacted by courts of the early modern period reflected the lack of economic value in human labor created by conditions of surplus labor supply, as feudalism broke down but before capitalism had produced a demand for unskilled labor. The trend toward leniency, which Durkheim had also observed, reflected the value of labor as commercial society began to develop and the population surplus declined through colonialism and the relocation of many laborers to the New World. New punishments, like convict transportation and houses of correction, emerged to use the labor of those undergoing punishment. These punishments, and the criminalization of vagrancy (the state of being unemployed), also helped to incentivize prospective workers to stay in the labor market instead of waiting for better conditions or higher wages. For Rusche and Kirchheimer (who wrote before World War II), the promise of penal welfarism to reform prisons along treatment lines which found reflection in the legal code of Weimar Germany and other European societies during the 1920s depended largely on the ability of global capitalism to escape crisis, and the success of the countermove toward penal harshness associated with the Nazi government in Germany.

Punishment may also serve a sophisticated political tool of class rule available to leaders attempting to mediate the conflicts inherent in class-divided societies like England during the rise of capitalism (Thompson, 1975; Hay et al., 1975; Linebaugh, 2006).

More recently, sociologists and geographers have suggested that mass incarceration in the late twentieth century reflects a strategy of control associated with globalization and neoliberalism (Garland, 2001; Western, 2006; Gilmore, 2007; Wacquant, 2009).

Toolkit Three: Punishment and Political Technologies of the Body

After Durkheim (1969) and Rusche and Kirchheimer (originally published 1939), there is a gap of some three decades until a reawakening of punishment and society scholarship.

During the high tide of scientific penology, most social scientific reflection on the social role of punishment and the causes of penal change was concentrated on the technical goal of testing and advancing methods of treatment presumed and required by the success of penal welfarism in the decades following World War II.

It is the crisis of this model, marked by prison disorders and outside political protests against the prison system, that sparked renewed interest in the Durkheimian and Marxist approaches. It also led to the development of a third approach by two independent scholarly projects, both inspired in large part by the political protests on behalf of prisoners and against the modern correctional establishments in France (Foucault, 1977) and Italy (Melossi and Pavarini, 1982). Both projects took the work of Rusche and Kirchheimer as a starting point, but taking political economy as a horizon, both independently examined the prison in its relationship to the disciplinary technologies of power, whose rise both in state agencies and in private business establishments was crucial to the successful organizing and protection of capitalism.

Prisons emerged from a now forgotten period of experimentation in punishment at the end of the eighteenth century, because they fulfill the judicial function of delivering painful (or at least distasteful) treatment on a mass scale without unduly disrupting the coordination demanded by capitalism and democracy.

Responding to Foucault (1977) and Melossi and Pavarini (1982), punishment and society scholars in the 1980s began a vigorous debate over whether rupture three, the development of twentieth-century practices, like parole, probation, and juvenile justice, should be seen primarily as an extension of the disciplinary logic of the prison (which Foucault suggested at the end of his book) or a radical transformation (Bottoms, 1983; Mathiessen, 1983; Shearing and Stenning, 2003; Cohen, 1985; Feeley and Simon, 1992). An alternative is to see rupture three as reflecting a fundamentally new technology of power, one associated with social and medical diagnosis, specialized treatment institutions, as well as social insurance and welfarism and what some sociologists of governance have called 'the social' (Donzelot, 1979; Rose, 1999).

The rise of mass incarceration at the end of the twentieth century, in the US and in some other countries, may reflect the influence of a new political technology, that of containment or waste management. These new techniques, coming from fields like private security, operations research, and cybernetics, emphasize incapacitation and control (Deleuze, 1992; Feeley and Simon, 1992; Garland, 2001; Young, 1999; Shalev, 2009).

Toolkit Four: Punishment and Civility

In his sweeping history of manners and state formation from the late Middle Ages through the eighteenth century, Norbert Elias (1978) laid the groundwork for a powerful account of increasing penal leniency (ruptures two and three). Observing what he called the 'arc of civility,' the spread of refined manners and diminishing violence that spreads from the aristocracy to the industrial working classes in a period of about 400 years, Elias theorized that growing centralized state control in the external world correlates to increasing internal psychological controls (and corresponding tensions and anxieties) within the 'civilized' human subject (Mennell, 1992). Building on Elias, historians and sociologists have generated substantial studies of the long-term development of punishment in Europe (Spierenburg, 1984, 1991, 2004; Garland, 1990; Pratt, 2007).

Drawing on Elias, Spierenburg (1984, 1991) has challenged the claims implicit in toolkit one (Rusche and Kirchheimer, 2003) and explicit in toolkit two (Foucault, 1977) – that penal change happens in a series of ruptures or sharp breaks with the past. Rather, according to this research, the decline of scaffold punishment and the rise of imprisonment were gradual changes reflecting slowly shifting social sentiments of citizens and especially elite actors rather than catastrophic failures of top–down control strategies (see also Masur, 1989; Gattrell, 1994).

John Pratt (2007) has applied Elias' theory to explicating the rise of mass incarceration, rupture four, as a 'de-civilizing' process. Pratt cogently argues that the civilizing process is not a one-way ratchet, and that the linkage between greater levels of state centralization of life and subjective pacification can unwind.

Although America has adopted more extreme punishments, it has not necessarily broken with the trends suggested by the civilizing process. David Garland's (2010) study of capital punishment in the United States during a period when, both in the scale of imprisonment and the persistence of capital punishment, the country seemed to diverge significantly from its peers suggests that the constraints of civility remain strongly at work. Rather than being an exception, the contemporary American death penalty, with its often excruciating search for certainty as to the degree of suffering experienced by prisoners during the execution, may exemplify the demands that the processes of state formation ultimately place on the exercise of state power.

Punishment and Legality

Punishment as a problem for modernizing societies has been a distinctly legal problem (Hart, 2012). The principle of legality can be traced through the history of Western penal practices since the end of the Middle Ages, and the progressive legalization of the power to punish has been a central finding of historical and sociological studies (Garland, 1990: p. 184; Weber, 1978: p. 37; Jacobs, 1977).

But punishment is a particularly fragile institution when it comes to legitimacy. The ways in which it can fail are multiple and its satisfactory completion often leaves many unsatisfied. This makes punishment among the most volatile and change-prone institutions of society. Indeed, the significant penal reforms in America's Early Republic period were preceded by mandates in states' new constitutions (Rothman, 1972; McLennan, 2008: pp. 21–22), while prison labor was authorized as the sole exception to the Thirteenth Amendment's prohibition of slavery (Lichtenstein, 1996; McLennan, 2008). More recently, conditions in super-maximum-security (supermax) prisons and secure housing units have been redesigned to hypercomply with Supreme Court ruling (Reiter, 2012).

For much of ruptures two, three, and four, national legislation and rights derived from national constitutions have been the crucial legal influence on penal practices. To these have been added in recent decades a body of human rights law

anchored in treaties as well as in a growing body of customary law. The prohibition on torture is considered a matter of customary international law obligatory on all state actors whether those under treaties, like the United Nations Convention Against Torture (1984). The Universal Declaration of Human Rights (1948) specifically provides that "No one shall be subjected to torture or to cruel, inhuman or degrading treatment or punishment." The International Covenant of Civil and Political Rights provides that: "The penitentiary system shall comprise treatment of prisoners the essential aim of which shall be their reformation and social rehabilitation" and which limits the death penalty (in those countries that have not abolished it altogether) to the most serious crimes. Some regional human rights treaties, like the European Convention on Human Rights, offer a particularly strong version of the interaction human rights law and modern penal practices (Van Zyl Smit and Snacken, 2009).

These norms, which are anchored in the broad concept of 'human dignity' (Whitman, 2003), have helped shape an emerging 'pan European penal sensibility,' which treats imprisonment as a last resort, requires that prisoners be kept in conditions as closely corresponding to community life as possible, and requires that prisoners be prepared for eventual reintegration into the community (Van Zyl Smit and Snacken, 2009). One of the most significant research questions of our time is whether greater court recognition of the human dignity of prisoners will counterbalance the pressures on penal bureaucracy coming from punitive populism in many contemporary societies.

Toolkit Five: Punishment and Culture

Wielding Durkheim, Marx, or even Foucault to explicate a particular penal policy or event can be less useful than finer tools of cultural and organizational analysis. Cultural sociologist Philip Smith (2013) argued that the theories mentioned earlier are most useful in making sense of what might be thought of as the 'penal climate,' that is, stable long-term patterns in the practices and discourses that define punishment in society, but less useful in making sense of the short- and medium-term developments. He provocatively analogizes these more temporary developments to the 'weather' while relating large-scale shifts to the 'climate' ('climate is what you expect, weather is what happens'). These include tools of narrative analysis that allow the analyst to unpack the meanings coded in the innumerable penal stories and statements that punishment gives rise to (Smith, 2008; Brown, 2009; Garland, 2010). It also includes sociological analysis of distinctions within social fields (Bourdieu, 1980; Page, 2013). Another important line of punishment and society scholarship connects cultural sociology to issues of social structure and class hegemony (Hall et al., 1978).

Part III. New Problems and Horizons of Punishment and Society

Punishment and Migration

In almost all the advanced economies of the world today, non-citizens are the fastest growing segment of the prison population (De Giorgi, 2006; Calavita, 2005; Melossi, 2013). Frequently, this incarceration is not considered 'punishment' as a legal matter because the detention is ordered on the basis of a 'civil' judgment that the person is in the country without proper permission and for the purposes of determining his legal status and deporting him; it is not a criminal penalty for a conviction. As a practical matter, immigration detention facilities are equivalent to prisons in their restrictions on liberty and interference with normal family and work life, while often lacking the programs and legal protections accorded to prisoners.

Mass Supervision/New Banishments

The rise of imprisonment rates in some advanced societies, and in particular the US (rupture four), seemed particularly surprising against the trends of the 1960s and 1970s, when institutional populations, including prisons, were declining in many advanced economies including the US and the UK (Cohen, 1985). In its place, forms of social supervision that emerged at the turn of the twentieth century (rupture three) were expected to become a more substantial part of the overall penal effort and with growing significance for the lives of people under legal sentence. During mass incarceration, parole and probation populations grew commensurately with prison populations, and increasingly became contributors to the growing prison population rather than an alternative to it (Simon, 1993; Petersilia, 2003).

Today it appears that many advanced societies that have avoided radical increases of imprisonment have greatly expanded the scale and reach of supervision, now often enhanced with electronic monitoring (Robinson et al., 2013; Nellis, 2010). Countries like the US that have experienced mass incarceration and its rising costs now seem poised to increase the role and power of supervision sanctions; a shift that could mark a return to twentieth-century norms, or a new form of 'mass supervision.' Researchers in the US have also noted the rise of spatial sanctions aimed at managing the access of individuals perceived as risky to social spaces (Beckett and Herbert, 2010).

Punishment, Risk, and Prevention

At least since the birth of the prison, rupture two, penal practices have been forward looking, acting not just to expiate past bad acts but to correct future behavior (Foucault, 1977). The late twentieth-century surge in imprisonment reflected a highly pessimistic assessment of the future dangerousness of prisoners (and pessimism about rehabilitative interventions), leading to a 'new penology' based on managing permanently high-risk populations through imprisonment (Hannah-Moffat, 2013; Feeley and Simon, 1992; Garland, 2001; Hudson, 2003; but see Lynch, 1998; Hannah-Moffat, 2004).

Conclusion

Research on the social and legal aspects of punishment has grown from a series of provocative social theories about Western state formation to an interdisciplinary field of

punishment and society research (Simon and Sparks, 2013). The field was initially concerned with the political claims of prisoners and the implications of the penitentiary project for the claims of welfare liberalism in the 1960s and 1970s. The rise of mass incarceration has been the primary focus of researchers since the late 1990s. As prison populations come down in the US, the field has recruited a large number of well-trained interdisciplinary students and is primed for a comparative and historical look beyond the ruptures in Western penality that have been its primary focus.

Abstract

American philosopher, Hilary Whitehall Putnam (1926–) is one of the most influential analytic philosophers of our time. He is particularly well known for his contributions to philosophy of science, philosophy of mind, and philosophy of language. His work is also marked by a critical engagement with his own earlier views and several changes of key philosophical positions. This article distinguishes between early, middle, and late periods in Putnam's writing and discusses the most seminal ideas of each period. Particular attention is paid to Putnam's treatment of the question of realism over the three periods.

Life

Hilary Whitehall Putnam is one the most influential and prolific analytic philosophers of our time. He has written extensively on a wide array of philosophical topics but is particularly well known for his contributions to philosophy of science, philosophy of mind, and philosophy of language. Putnam was born in Chicago in 1926, but the family soon moved to Paris where his father, the eminent translator and literary editor Samuel Putnam, was to translate the complete works of Rabelais and edit the *Paris Review*. In 1933, the family returned to the United States and eventually settled in Philadelphia where Putnam lived until his graduation from the University of Pennsylvania in 1948, with a degree in Philosophy, Linguistics, and German. After a year in Harvard, Putnam moved to UCLA in 1949 to do a PhD under the supervision of the eminent logical positivist Hans Reichenbach. Reichenbach's profound influence led to a lifelong preoccupation with philosophy of physics and mathematics, and increasingly critical engagements with logical positivism.

Putnam's early academic career was at Northwestern (1951–52) and Princeton University (1953–61) followed by 4 years in MIT (1961–65), where he was Professor of Philosophy of Science and instrumental in setting up a new department of Philosophy. From 1965 until his retirement, Putnam has been a member of the Department of Philosophy in Harvard, first as Walter Beverly Pearson Professor of Modern Mathematics and Mathematical Logic and later as the Cogan University Professor. He is a Fellow of the American Academy of Arts and Sciences, a Corresponding Fellow of the British Academy, and was a president of the American Philosophical Association (Eastern Division). His numerous awards include the Rolf Schock Prize in Logic and Philosophy from the Royal Swedish Academy and The Ulysses Medal from University College Dublin, Ireland. He is married to the philosopher Ruth Anna Putnam.

Work

The sheer breadth and variety of Putnam's writing, accompanied by a radical practice of rejecting or reformulating his own earlier positions, make the task of summarizing and evaluating the full span of his work difficult, if not impossible. This article distinguishes between the early, middle, and late periods in Putnam's writing – what I call Putnam 1, 2, and 3 – and discusses the most seminal ideas of each period. Despite frequent changes of views and philosophical orientations, however, a number of prominent themes are evident in Putnam's writing, among them are the questions of realism and its discontents, a preoccupation with questions about the status of science, a continuous concern with questions of norms and values, and a general aversion to dichotomized thinking.

Early Putnam

Putnam's early publications have the imprint of his encounter with Rudolf Carnap, the most important of the logical positivists, whom he came to know during his Princeton years. Two topics were central. The first was on questions of synonymy and analyticity, the topic of W.V.O. Quine's seminal "Two Dogmas of Empiricism" (Quine, 1951), where Quine had argued, against Carnap, that the distinction between analytic and synthetic statements, or sentences true by virtue of their meaning only versus those true by virtue of facts, is untenable. Putnam's *The Analytic and the Synthetic* (1962) is where he establishes his own distinct philosophical voice. The article is also the first clear example of Putnam's aversion to philosophical dichotomies and beginnings of a lifelong critique of logical positivism. Putnam agrees with Carnap that there is an obvious and "gross distinction between 'All bachelors are unmarried' and 'There is a book on this table'" (1975b: 36). However, he is also in agreement with Quine that "'overworking the analytic–synthetic distinction' distorts our views of its significance for science or Philosophy" (1975b: 33). The distinction, he argues, could have a role provided that we do not treat it as a sharp dichotomy but as a continuum. There is a small group of concepts, he calls them 'one-criterion concepts,' which have a single criterion for application. For instance, the only criterion for the application of 'bachelor' is that of being an unmarried man and we cannot abandon this criterion without depriving 'bachelor' of its use, hence the analyticity of 'all bachelors are unmarried men.' A majority of concepts, on the other hand, are 'law cluster' concepts where "any one law can be abandoned without destroying the identity of the … concept involved" (Putnam, 1975b: 52). He thus

shows a way of thinking about the Quine–Carnap debate that retains the initial insight of the defenders of analyticity while avoiding its philosophical pitfalls.

The second area of focus in this early period was mathematics and its philosophy. Putnam's copublication of the proof of "Hilbert's Tenth Problem (1961)," in collaboration with Martin Davis, established his reputation as a mathematician. A collection of articles on philosophy of mathematics, coedited with Paul Benacerraf in 1964, was his first book-length publication. Putnam, in that early period, was a realist about both mathematics and science but his realism about mathematics piggybacks on realism about science. In what has become known as the "Quine–Putnam Indispensability Argument," Putnam, in similar lines of thought put forward by Quine (e.g., Quine, 1960), argues that much of science is either expressed in mathematical terms or uses mathematics as an indispensable component. And to the extent that scientific hypotheses are true, in the sense of corresponding with a mind-independent reality, then so are the mathematical theorems that underpin it. He says, "quantification over mathematical entities is indispensable for science, both formal and physical: therefore we should accept such quantification; but this commits us to accepting the existence of mathematical entities in question" (Putnam, 1972: 57). A realist interpretation of science, thus, supports realism about mathematics.

Science

Putnam's key idea on realism about science is known as the 'no miracle' or Putnam–Boyd argument to the best explanation. Using an abductive format and taking a similar approach to the indispensability argument for mathematics, Putnam and Boyd argued that the best explanation for the predictive and explanatory success of a scientific theory is its truth or approximation to truth. Their argument, in a nutshell, states that

1. Mature, that is, well-supported, and long-established scientific theories, result in successful predictions.
2. The best explanation for these predictive successes is that such theories are true or approximately true, i.e., they reflect what is going on in the natural world.
3. Nonrealist arguments, such as instrumentalism, cannot explain the success of science.

Therefore, mature scientific theories are (approximately) true.

Scientific realism is the claim that mature scientific theories are true.

Therefore, scientific realism is true.

Putnam explains:

> The positive argument for realism is that it is the only philosophy that does not make the success of science a miracle. That terms in mature scientific theories typically refer (this formulation is due to Richard Boyd), that the theories accepted in a mature science are typically approximately true, that the same term can refer to the same thing even when they occurs in different theories – these statements are viewed not as necessary truths but as part of the only scientific explanation of the success of science, and hence as part of any adequate description of science and its relations to its object

Mind

Putnam's other major contribution in this period was to philosophy of mind. The two dominant theories of the mind in the second half of twentieth century were logical behaviorism, which reduced the mind to dispositions to behavior and patterns of stimulus and response, and mind–brain identity theory claimed that mental states are identical with states of the central nervous system. Putnam, starting in the 1963 article "Brain and Behavior," republished in Putnam 1975a, argued that the view that a mental state, such as experiencing pain, can be reduced to certain types of behavioral states is untenable because it ignores the fact that pain is a private sensation. Identity theory is also defective because it disallows the possibility of ascribing mental states, such as pain, to creatures with a physical makeup different from that of humans. If pain is identical with certain neuronal activities in the human brain, then creatures with no such neurons would not be capable of experiencing pain.

Functionalism was Putnam's positive contribution to philosophy of mind. His version of the theory is known as Machine Functionalism because of the parallels he draws between mental states and the functional states of universal Turing machines or computers. A mental state is characterized by its causal relations with external stimuli, or input from the senses, behavioral responses, and relations with other mental states, e.g., beliefs and desires. Mental states are the causes of our actions within the background of our beliefs and desires about the world, but are not reducible to behavior. Even sensations, such as pain, could be explained functionally. Things that feel pain do so not because of the particular brain state they are in, but because they are in a certain functional state. One strength of Functionalism is that it ensures the autonomy of the mind and shows that "[t]he question of the autonomy of our mental life does not hinge on and has nothing to do with that all too popular… question about matter or soul-stuff. We could be made of Swiss cheese and it wouldn't matter" (Putnam, 1975a: 302). Just as different machines need not share the same hardware to carry out the same computation, mental states, including sensations and emotional states, could be functionally alike but physically different. What matters, Putnam argued, is functional organization, which is realizable in very different hardware, be it by silicon-based robots or by Martians with a different evolutionary history and biological makeup. The 'multiple realizability' of mental states became orthodoxy in cognitive science.

Decades later, Putnam would repudiate functionalism for reasons that are quite similar to his rejection of behaviorism and identity theory (Putnam, 1987b, 1992a). Earlier Putnam had rejected a reductionist account of the relationship between the mind and brain, he now warns against the reduction of mental states to machine states or brain software. In the same way that mental states cannot readily be identified or corelated with behavioral or brain states, mental and psychological states, such as hoping, desiring, fearing, etc., also cannot be corelated to software in a straightforward singular manner. In arguing against mind–brain identity theory, Putnam had maintained that mental states are multiply realizable because they are 'compositionally plastic.' He now believes that mental states are also 'computationally plastic' because a propositional attitude, such as a belief, can be realized by many different

computational states (Putnam, 1994: 47). The morale is that intentional mental states cannot be reduced to either physical or computational states.

Language

Putnam's contribution to philosophy of language has been momentous. For much of the twentieth century, philosophy of language was dominated by what is commonly known as 'descriptivism' – the approach to meaning adopted by the founders of analytic philosophy, Gottlob Frege and Bertrand Russell. According to descriptivism, names refer to what they stand for via what Frege calls 'sense' or conceptual content and what Russell calls 'definite descriptions.' For Russell, for instance, what defines 'gold' is a conjunction of properties such as its color, texture, weight, etc.; 'gold,' thus, is a shorthand term standing for a longer list of the properties we associate with that substance. Meaning, thus, is distinct from reference and is mediated by descriptions of that reference. Putnam and Saul Kripke, in his *Naming and Necessity* (1980), turned this position on its head.

In "The Meaning of 'Meaning,'" Putnam sets out to refute what he sees as a 'grotesquely mistaken' view of language (1975a: 21) arising from the tendency to ignore the role of the natural and social environment in establishing the meaning of words in general and names in particular. Two incompatible assumptions are at fault, he says. First, that to know the meaning of a term is to *be* in an appropriate psychological state and second, that meaning determines reference. Traditional theories of meaning are unsatisfactory because they are individualistic rather than social and neglect the contribution of external reality to meaning. The crucial point missed by descriptivism was that both the reference and meaning of natural kind terms, 'water,' 'gold,' 'brain,' for instance, are determined through interactions between these physical entities and referring minds, i.e., language users.

Putnam's argument proceeds through several thought experiments, the best known of which is the Twin Earth thought experiment, where he asks us to imagine a distant planet identical in most respects to our planet. Twin Earth has the same geographical features as earth – seas, lakes, mountains, etc., it has a climate similar to earth, and its inhabitants seem to speak the same languages that the earth people do. The one major difference with earth is that the stuff in their lakes and oceans, used for drinking, bathing, and swimming, does not have the chemical constitution H_2O but is XYZ. Except for having a different underlying chemical composition, XYZ resembles earth water in all respects, Moreover, the word used by Twin Earthians to refer to XYZ is 'water.' However, according to Putnam, when the inhabitant of the Twin Earth utter a sentence such as 'bring me a glass of water,' they are referring to XYZ, while when an earthling utters the same request she is talking about H_2O. So, the two seemingly identical sentences are about two very different things, and hence they have different meanings. The Twin Earth person is in effect talking about Twin Earth water or twater and not water.

According to Putnam, natural kind words have an "unnoticed indexical component: water is stuff that bears a certain similarity relation to the water around here" (1975a: 234). The reference of the term 'water,' has been fixed by pointing out to a stuff and saying something like "this is water" (Putnam, 1975a: 231). This initial baptism and the continuity of usage have establish causal connections between the speakers and what they are talking about. People on earth and Twin Earth may have the same kind of mental images running through their head when they think, respectively, of water and twater. Yet 'water' in English has a different meaning from 'water' in Twin Earth English. Thus, meaning is independent of the 'inner' mental states that people possess; rather, it depends on external, natural, and social factors. As he famously puts it "cut the pie any way you like, 'meanings' just ain't in the *head!*" (Putnam, 1975a: 227).

Not all language users would have knowledge of the underlying composition of natural kinds or always be able to always identify such kinds accurately. Putnam introduces the idea of division of linguistic labor to explain such cases (1975a: 227). Words, he argues, have producers and consumers, the experts and the ordinary users of language. The users often know only the stereotypical descriptions associated with a natural kind term and sometimes they get even those wrong. One role of stereotypes is to facilitate communication between speakers who ordinarily have very little knowledge of the underlying structure of natural kinds. To find out whether a particular object falls under a natural kind term users have to defer to the knowledge of the experts. For instance, ordinary speakers know gold through the stereotypical properties (shiny, yellowish, precious metal), but in order to authenticate whether a piece of metal is gold they defer to the superior knowledge of the relevant experts.

The Twin Earth thought experiment has become a paradigm of philosophical methodology in the analytic tradition and its use has been extended beyond the semantics of natural kind terms to ethics, philosophy of mind, and theories of content, despite many changes of position over the years, Putnam has remained constant in defending the view.

Middle Putnam

A preoccupation with what Putnam calls the "great question of realism" (Putnam, 1994: 295) or the question of how language connects with the world, is a unifying thread in Putnam's work, but the issue takes center stage in Putnam 2. The early Putnam was a realist not only about the existence of material objects but also about mathematical and purely theoretical entities such as numbers, fields, and physical magnitudes. The most striking feature of Putnam's work in the middle period is the rejection of some of the core assumptions of realism that he had previously embraced.

The emergence of Putnam 2 can be dated back to the presidential address he gave at the Eastern Division of the American Philosophical Association in December 1976, subsequently published as "Realism and Reason" (1977). Putnam used the occasion, rather dramatically, to repudiate his earlier views, a position he came to call 'metaphysical realism.' Metaphysical realism, he has argued, is committed to the following:

a. The world consists of a fixed totality of all objects.
b. The world has a fixed totality of properties.
c. There is a fixed set of 'language-independent' objects (some of which are abstract and others are concrete) and a fixed 'relation' between terms and their extensions.

d. There is a sharp distinction between properties we discover, the factual, and the properties we project onto the world (i.e., the evaluative).
e. There is a fixed relation of correspondence in terms of which truth can be defined (Putnam, 1981: 43 and 1999: 183).

Putnam offers several arguments to show the incoherence of metaphysical realism, the earliest and most controversial of which is the model theoretic argument. The argument was presented in three different formulations and, at least initially, relied on the *Löwenheim–Skolem* theorem in mathematics (Putnam, 1977). The most influential version is the permutation argument (Putnam, 1981) where it is claimed that it is possible to systematically permute the way singular terms and predicates refer without changing the truth values of the sentences containing these terms. The argument particularly targets the metaphysical realist's assumption that there is a fixed 'relation' between terms and their extensions (c above) and, that there is a fixed relation of correspondence between propositions and states of affairs (e above). Take any epistemically ideal theory, one that meets all operational and theoretical constraints possible, for instance it is consistent, complete, well formulated. According to the metaphysical realists, for such a theory to be true then it also should satisfy a unique word–world relationship, i.e., its terms should refer determinately to objects and entities (or classes of objects) in the world. However, Putnam contends that there could be no such thing as determinate reference as required by the realists. Any assignment of truth, by envisaging a relationship of reference, presupposes an interpretation of the referring language; the model theoretic argument shows that for any given language there could be many such interpretations and consequently many different ways of assigning (correct) reference. Consider Putnam's example of 'the cat is on the mat.' The sentence comes out true in an interpretation where 'cat' refers to the animal cat and 'mat' to an object we put on the floor, but it also comes out true if we use an alternative interpretation where 'cat' refers to leaves and 'mat' refers to trees. Thus metaphysical realism is shown to be based on an incoherent demand. It may be argued, using Putnam's own externalist theory of meaning, that 'cat' refers to cats not to leaves because it stands in the appropriate causal relation to cats and not to leaves. Putnam responds "How 'causes' can uniquely refer is as much of a puzzle as how 'cat' can on the metaphysical realist picture" (1978: 126). To think that there is metaphysical glue binding 'cat' to the animal cat is to subscribe to "a magical theory of reference" (1981: 47).

Putnam's second major argument against metaphysical realism is the famous brain in the vats argument (Putnam, 1981). The structure of the argument is quite simple. To believe that the world is mind-independent, as the metaphysical realist does, is to allow for the possibility of being radically mistaken in our beliefs about that world. Relying on a technologically updated retelling of Descartes' evil demon argument, Putnam proposes a matrix-type scenario, where the skeptic challenges us to prove that we are not brains kept alive by mad scientists dreaming of what we call 'reality.' He draws on arguments from semantic externalism to prove that such a scenario is incoherent and therefore so is metaphysical realism. As we saw, according to semantic externalism, the reference of words is at least partially determined by relations between language users and the natural and social world they inhabit. The word 'tree,' in a speaker's mouth, refers to the object tree because of a variety of social and physical connections with trees in the world. The same is true of the words 'brain,' 'vats,' etc. But if we were brains in a vat, we could not possibly be using the word 'brain' the way unenvatted people use for there are no actual connections between the brains in vats and their brains or vats. The words 'brain,' 'vat,' etc., as uttered or thought by brains in vats, would be connected only to neural impulses or images of brains and not to real brains in real-life vats. The skeptical hypothesis therefore is either false or cannot be coherently stated. But if the skeptical hypothesis is incoherent, then so is metaphysical realism.

Internal Realism

'Internal realism' is Putnam 2's proposed alternative to metaphysical realism, where, under the influence of Michael Dummett, in place of his earlier correspondence theory, he advocates an epistemic view of truth. Internal realism is committed to the following three core doctrines:

1. There is more than one true theory or description of the world.
2. There is no 'ready-made world.'
3. "truth is an *idealization* of rational acceptability – some sort of ideal coherence of our beliefs with each other and with our experiences *as those experiences are themselves represented in our belief system* – and not correspondence with mind-independent or discourse-independent 'state of affairs'" (Putnam, 1981: 49–50).

A crucial feature of internal realism was its commitment to an epistemic view of truth. Truth, Putnam 2 argued, is not independent from knowledge, but at the same time, it should not be identified with contingent and changeable epistemic achievements of a single time and a place, but with what we can know and justify under ideal epistemic conditions. The assumption is that if there were such things as epistemically ideal conditions, then statements that were justified under such conditions would be true. As Putnam puts it, truth is independent of justification here and now, but not independent of all justification (Putnam, 1981). This view aimed to deal with the problem of access by minded beings, such as us, to a mind-independent world. We cannot step outside our language, our mind-set or perspective and compare our beliefs about the world to the world as it is in itself. To give any substance to such a view we need to postulate a God's eye view of reality, a view not accessible to us mere mortals. The epistemic view of truth bypasses the need for a God's eye perspective while allowing for the possibility of objectivity in truth and knowledge.

The second important component of internal realism is conceptual relativity, the view that there could be alternative, noncompatible descriptions of objects and their properties. The key motivation for conceptual relativity is the conviction that the very *idea* of an unconceptualized world is incoherent. All our experiences of the world are shaped by our concepts, here too we cannot have a God's eye point of view, but only "the various points of view of actual persons reflecting various

interests and purposes that their descriptions and theories subserve" (Putnam, 1981: 50).

To show the force of the argument Putnam proposes a scenario where one and the same situation can be described as involving very different numbers and kinds of objects (Putnam, 1987a, 1990b). Let us take a world containing objects a, b, c. Our usual way of counting tells us that there are three objects in that world. However, according to 'mereology,' a theory of part/whole relationship first formalized by the Polish logician Stanislaw Leśniewski in the early twentieth century, for every two particulars there is an object that is their sum. Given this basic mereological starting point, the world just described will contain not three but seven objects. Putnam asks: Faced with a world with three individuals, does the question how many objects are there in this world have a determinate reply? The answer is no, because any reply would depend on how we interpret the word 'object.' From an atomist perspective, the perspective most of us take for granted, there would be three independent, unrelated objects a, b, c in this world. While, according to the mereological conceptual scheme the world will consist of seven objects, a, b, c, a + b, a + c, b + c, a + b + c. The example makes the internal realist's point that we cannot coherently talk of a world consisting of language-independent objects or properties for the very idea of object is mediated by the concepts we use.

In the late 1980s, Putnam reached the conclusion that internal realism, and its epistemic view of truth, in particular, faced problems similar to those besetting metaphysical realism and its concomitant correspondence theory of truth. The metaphysical realist needs to explain how access to the external world is possible, how the human mind could reach out, so to speak, and touch or represent a mind-independent world. Putnam came to believe that there was a similar problem in explaining our "referential access to 'sufficiently good epistemic conditions'"(Putnam, 1994: 462). The growing concern with this question led to the emergence of a third phase in Putnam's philosophical journey.

The Later Putnam

The emergence of Putnam 3 can be dated to his 1990 Gifford lectures in St. Andrews University. Ongoing change of position, however, particularly in comparison with the more radical break between Putnam 1 and 2, has been more nuanced and gradual. Putnam 3 defends what he variously calls 'common sense,' 'natural,' or 'pragmatic realism' and rejects both his early metaphysical realism and the later epistemic view of truth. While internal realism, at least in its inception, had a Kantian flavor; Putnam's work in the 1990s was influenced by Wittgenstein and by Pragmatism. The most crucial feature of this latest philosophical project is "a recovery of the natural realism of the common man" (Putnam, 1999: 24).

In earlier work, Putnam had treated sensations as the interface between the human mind and the external world. By early 1990s, however, he came to find this option unworkable – a realization that set the scene for the gradual emergence of his third reply to the big question of realism. Natural or Pragmatic realism emphasizes the role of our direct, unencumbered, contact with the world, unhampered by sense data or any other intermediaries. We can be natural realists because we perceive the world itself, and not the sense data caused by that world. Natural realism, Putnam claims, reflects our common sense "that 'external' things, cabbages and kings, can be *experienced*." (Putnam, 1999: 20).

One important feature of his thinking in this phase, and a carryover from Putnam 2, concerns the role and status of values in a world of facts. Putnam first questioned the intelligibility of a sharp division between factual statements and normative judgments, so popular among the logical positivists, in 1986. Some of his more recent publications (Putnam, 2002, 2004, 2012) deal in greater detail with the same theme. Putnam's aim is to dispel the wide-spread beliefs that while science deals with objective facts, moral values are purely subjective. Here, as in much of his writing in this phase, Putnam credits his views to classical Pragmatists such as William James and John Dewey.

Since David Hume's argument concerning the logical gap between 'is' and 'ought,' the fact/value division has been a cornerstone of naturalist or scientific worldview. Putnam argues that this orthodoxy is the wrong starting point for understanding both science and ethics. It is often claimed that scientific statements have a representational content; they represent states of affairs, while value judgments express our attitudes and emotions and give prescriptions and commands. For this reason, factual judgments are objectively true or false while ethical positions are projections and expressions of our subjective preferences. Putnam's key argument against this popular position is that the distinction is unsustainable because factual statements, as well as the practices of science, which enables us to decide what counts as a fact, are always value laden, in the sense that they presuppose some epistemic values (Putnam, 1981: 128). In other words, the very act of theorizing about the factual world is a value-laden activity. Here, once again, we see Putnam's desire "to break the grip that a certain picture has on our thinking; the picture of a dualism, a dichotomous division of our thought" (Putnam, 1987a: 71).

Conclusion

Philosophy for Hilary Putnam is an ongoing project involving a critical but generous engagement with numerous philosophical ideas and perspectives, including those of his older self. It is a never-ending attempt at renewing the subject matter and acknowledging our fallibility in the face of the formidable task of addressing some of the most fundamental questions facing us. The best summary of Putnam's approach to philosophy is by Paul Franks, one of his many students to have become prominent philosophers in their own right. Franks says, "Putnam is not best understood in terms of his 'position' or 'positions' but in terms of the dialectical tensions and complexity that expresses themselves through his positions" (quoted in Putnam, 2012: 2). This article has been a summary of both his various influential positions and the dialectical relations between them.

Qualitative Methodology in Developmental Psychology

Abstract

Qualitative methodology presently is gaining increasing recognition in developmental psychology. Although the founders of developmental psychology to a large extent already used qualitative procedures, the field was long dominated by a (post) positivistic quantitative paradigm. The increasing recognition of the sociocultural embeddedness of human development, and of the importance to study individuals' subjective experience, however, calls for adequate methodological procedures that allow for the study of processes of transformation across the life span. The wide range of established procedures in qualitative research offers a promising avenue to advance the field in this direction.

Qualitative research is composed of many different procedures to collect and analyze data. In addition to some general common premises, these procedures are based on distinct theoretical approaches (e.g., social constructionism, ethnomethodolgy, hermeneutics, symbolic interactionism, phenomenology, psychoanalysis) to give access to the social, cultural, and psychological realities of the individuals or groups of individuals (e.g., for an overview, see Flick et al., 2004). A number of handbooks of qualitative research exist in the field of psychology (Camic et al., 2003; Forrester, 2010; Lyons and Coyle, 2007; Smith, 2008; Willig, 2008; Willig and Stainton-Rogers, 2007) and several chapters are dedicated to qualitative research in the recent American Psychological Association handbook of research methods in psychology (Cooper, 2012).

This article outlines how qualitative methods can be applied fruitfully – in particular in the field of developmental psychology – by adopting a life-span perspective and considering different contexts of development and different fields of research. To do this, we first give an overview of the history of qualitative research in developmental psychology and introduce some general shared premises of qualitative methodology; we next present an overview of established procedures suitable for collecting and analyzing qualitative data in developmental research.

The New Interest in Qualitative Developmental Research

Qualitative methods are presently gaining increasing recognition in developmental psychology. This development can be related to the following reasons: for decades, the field – like psychology in general – was dominated by a positivistic and postpositivistic paradigm and accordingly by quantitative methods, such as experiments, surveys, and objective testing. The focus was primarily on age-related cognitive competencies and their effects on some aspects of social and nonsocial behavior with the aim of identifying general laws of development. Underlying this focus was an understanding of development as a series of universal and natural ('biologically based') processes within the child that are largely independent from historical and cultural contexts. These ontological and epistemological assumptions have been challenged within recent years by a paradigm shift toward an interactional and sociocultural understanding of human psychological functioning and in line with a social constructivist epistemology. Human development now is acknowledged to be inseparably and dialogically intertwined with individuals' participation in mundane everyday social interaction. Through repeated participation in social interaction individuals learn to make sense of their experience and gain an understanding of the world. Hence, increasingly it is acknowledged that human development cannot be understood adequately without taking its cultural embeddedness seriously. Social interactions are always culturally prestructured and the interpretations offered always are constructed culturally versions of the world. This line of reasoning makes developmental psychology inseparable from cultural psychology that is interested in meaning-making processes that occur in social interactions and everyday contexts. Psychological subjects, such as the mind and the self, are conceived of not as entities but as processes that are constituted, or made up, within specific social and cultural practice. Culture is seen as the human ability to draw on interpretative procedures to make sense of one's experience in social interaction, which in turn is embedded in a specific structure of social organization of the society in which someone lives.

Awareness is increasing that mainstream developmental psychology has failed to adequately describe and understand children's ordinary lives and their active participation in their social worlds. Rather than treating children as 'objects' of

 http://dx.doi.org/10.1016/B978-0-08-097086-8.23156-5

research, a stronger focus on the study of their subjective experience is required (Greene and Hogan, 2005; Burman, 2008; Mey, 2010; *see* Street Children: Cultural Concerns). This critique arose with the increasing recognition that individuals are actively acting and potentially self-reflexive subjects and constructors of their own life. Thirty years ago, Urie Bronfenbrenner (1977: p. 513) got at the heart of this critique with his well-known statement: "it can be said that much of developmental psychology, as it now exists, is the science of strange behavior of children in strange situations with strange adults for the briefest possible periods of time."

Both a dialogical understanding of human development and culture and a recognition of the importance of individual's subjective experience require rethinking the adequacy of prevailing methodological standards. In fact, the very object of developmental psychology – processes of change with age in the psychological functioning of individuals – requires a discrete research program based on a methodology and methods that allow for the study of these developmental processes. Much of the twenty-first century's developmental psychology's standardized methods, however, still are borrowed from the realm of nondevelopmental psychology and hence largely inadequate to capture developmental processes (Valsiner, 2000).

Accordingly, methodological procedures within a qualitative paradigm that aim at reconstructing developmental conditions and contexts, life stories, and individual experiences from the subjective perspective of the participants, as well as sociocultural coconstruction processes of meaning-making, increasingly are called for (Mey, 2010; Valsiner, 2000; Greene and Hogan, 2005). Although neighbor disciplines like sociology, educational science, linguistics, and anthropology have well-established research procedures to study individuals' perspectives and everyday lives across diverse age-groups, mainstream developmental psychology, especially in North America where most developmental research takes place, has long been unaware of these challenges and methodological consequences. Recently, however, the field has seen an emerging period of critical self-reflection and change and a new reorientation toward qualitative methods.

Pioneers of Qualitative Developmental Psychology

Developmental psychology, in fact, often has benefited from qualitative research: Several of the founding fathers and mothers of the discipline applied distinct interpretative procedures in their work, albeit not in such a systematic way as would be the standard for qualitative methods. They provided many arguments for the establishment and the development of a qualitative developmental psychology, although they never used the label qualitative themselves (for a further discussion of the historical development, see Mey, 2010).

These early works were in line with the main stances of qualitative methodology: They followed a knowledge-producing and theory-generating logic (rather than testing existing theories and ex ante formulated hypotheses). They developed theoretical stances strictly from the perspective of the individuals; they tried to avoid artificial settings and to do research in the everyday context of the individuals; and they reflected the process of production and construction of the data, mostly detailed and in a way of thick description using only a small number of cases.

Taking this into account, it can be stated that some of the most influential developmental theories are derived from qualitative research (e.g., Erikson's theory of psychosocial development, Piaget's theory of cognitive development, Kohlberg's stages of moral development). Although the work is quoted widely in the field, little is mentioned about the methodological approaches they used to come to their conclusions.

Other examples of early ethnography of the children's concrete everyday lives with the aim of setting a counterbalance to the prevailing mainstream in the discipline at the time are the diary studies of their own children by Darwin and Preyer at the end of the nineteenth, and by Clara and William Stern at thebeginning of the twentieth century. They kept a separate record for each of their three children that allowed for individual case studies. Only in a second step was the data discussed in relation to a broader theoretical context. In William Stern's approach – the theory of personalism – a qualitative research style was embedded from the very beginning, a fact that often remains unmentioned, while at the same time, Stern often is acknowledged as the one who coined the term 'intelligence quotient'.

Similarly, the ethnographical work on life space of urban children by Martha Muchow, a research associate at Stern's Hamburg Institute is an example of the groundbreaking work in the first decades of the last century. Muchow used different open-ended methods like participant observation, conversations, methods based on essays next to the analyses of documents, and standardized methods. She acknowledged that to understand the particular nature of children requires one to understand the difference between adults (also researchers) and children, a position that also is crucial for contemporary research in the interdisciplinary field of children and childhood studies and children's rights (e.g., see Burman, 2008; Greene and Hogan, 2005). Kurt Lewin's renowned film of a young child learning to sit on a stone that demonstrates the barriers and field forces at play is another example of a radical departure from orthodox research methodology that arose from a dissatisfaction with the apparent triviality of much experimental psychology at the time.

Jean Piaget – probably the most prominent developmental psychologist of the twentieth century – postulated a clear qualitative perspective in his theory of genetic epistemology and his innovations of methods. His research can be described as a version of ethnography: For instance, in his clinical method, Piaget expanded the boundaries of the experimental approach to include context-specific tasks that can be applied to children in everyday life settings. He also considered standardized observations to be unsuitable for the study of child development. According to Piaget, traditional test procedures – such as intelligence test items – fail to address relevant questions, such as inquiry into children's spontaneous interests and their emerging entirely original understandings.

Similarly, Lev Vygotsky's reflections on (developmental) psychological hermeneutics – laid down in his work in 1930s – show how developmental psychology can be built only on qualitative grounds. His demand was that a psychology that wants to investigate 'whole objects' in their complexity requires analysis into units (rather than into elements) while at the same time preserving the whole objects in their complexity. Two case studies presented by Vygotsky's partner Alexandr

Luria – in the context of his 'romantic science' – in the second half of the twentieth century are brilliant examples of longitudinal studies that are informative for a qualitative developmental psychology. One of these case studies, described in his book *The Man with a Shattered World*, is about a man who suffered a left brain injury from shell splinters during World War II. The study that is based on more than 3000 pages of diaries and annotations by Luria captures the development of a man over a time span of 25 years. Erikson's biographical reconstructions – beside his identity theory based on his work as a psychoanalyst – of the lives of prominent persons like Luther or Gandhi, can be seen as movement in this direction.

To define and found a qualitative developmental psychology, including rethinking the theoretical and methodical assumptions, it is essential to remember one's own research tradition. From a twenty-first-century perspective, this early works reveals an understanding that already points to central features of qualitative research, such as wholeness and holistic methods, historicity, and reference to single-case studies, and it is linked closely to some more general premises of a qualitative approach outlined in the next section. Moreover, although early works of developmental psychology focused on early and middle childhood, the field has expanded to include human development over the entire life span.

General Methodological Premises of a Qualitative Developmental Psychology

Since the early days of developmental psychology, a number of systematic procedures have been established based on general premises of a genuinely qualitative paradigm that allow for empirically sound studies. Although these principles make clear that qualitative methods need to be understood on their own epistemological terms, they also can be fruitfully combined with quantitative methods. Within a qualitative paradigm, systematic integration of different procedures is understood as taking different perspectives on the investigated phenomenon to provide a holistic description of the phenomenon. This differs from triangulation approaches that are concerned with the mutual validation of findings or with cross-validation, as found in many mixed-methods studies that are oriented more toward a quantitative paradigm. A genuinely qualitative research style aims to overcome an abstract notion of development, as defined by the increase or decrease of specific abilities or by the transition from one hypostatized development stage to another. Such a style pursues a holistic view of abilities and functions within a developing person and between a developing and actively constructing person in a developing environment. To adequately access individuals' perception, description, and interpretation of reality, it is committed to the following three general and central principles of qualitative research (see also Flick et al., 2004).

The Principle of Openness: Individuals' Perspectives

Qualitative research generally follows an inductive-deductive and theory-generating logic. The guiding principle of openness aims to appropriately reconstruct (subjective) reality from the subjects' perspectives. The aim is to use this as a basis to (further) generate theories, to attain thick descriptions of developmental–psychological phenomena, and to understand the possible different development paths (that run parallel). Theoretical preconceptions by the researchers in qualitative research are understood to be 'sensitizing concepts' that can be used fruitfully in the analysis. This is in stark contrast to the traditional conception of development as more or less linear finality (that is defined ex ante from the perspective of the researcher).

The Postulate of Foreigness – Diversification and Development

The postulate of foreigness is linked closely to the principle of openness. This approach prohibits the researcher from (self-evidently) equating his or her own concepts (of development) with those of the culture, group, or person studied. This is an essential principle in cultural developmental psychology and childhood studies in which he difference between children and adults becomes evident when the 'culture of the child' meets the 'culture of the adult' (see Burman, 2008). A qualitative approach helps to prevent researchers from confusing their experiences and concepts with those of the children researched. At the same time, children and childhood studies and related areas of research pose an exceptional challenge for qualitative research as, until now, it has been much focused on language. Forms of expression typical for children can be of limited verbal nature and therefore it often is necessary to interpret preverbal articulation, gestural symbolizations, playful expressions, and the like. Research from the 'perspective of the children' or the 'aging people' is not possible without additional reflection on the researcher as a person, the way he or she is conducting the research, and consequently the conditions under which scientific knowledge is generated.

The Principle of Communication – Development as a Process

The relationship between the researcher and the researched also is reflected in the principle of communication. This principle is based on the assumption that all data are jointly constructed by those involved in the situation. Every research situation entails an intervention and hence a modification of the object of research. The principle of communication plays a pivotal role within process analysis and the development of process models, one main task of a qualitative developmental psychology, as it enables one to adequately conceptualize data as having a temporal dimension: that is, data in time that can be analyzed in a sequential and developmental–psychological manner. Any research situation hence needs to be understood not as a unit but as a sequence of events, taking place between those (researchers and researched) involved, that can be analyzed.

Qualitative Methods in Contemporary Developmental Psychology

As becomes clear from the overview of the historical roots of the field, a number of qualitative methods can be applied fruitfully to developmental psychology research in terms of studying processes and transformations across the life span. Moreover, the

number of established procedures in qualitative research is expanding (see Flick et al., 2004 for an overview). Qualitative research is a heterogenous field; however, besides the general premises they share, these methods need always to be understood within the respective theoretical and epistemological backgrounds in which they were developed. This implies that some methodologies in qualitative research need to be considered as approaches or research styles rather than as specific methodological procedures, which makes it difficult to allocate them exclusively as procedures for data assessment or data analysis. Overall, however, it is crucial that procedures of data assessment fit the procedures of data analysis with regard to their epistemological stance.

Procedures for Data Assessment

Interviews

Interviews are the most commonly used methods in qualitative research (for an overview, see Flick et al., 2004) and also are prominent in developmental psychology. Some early ambassadors of developmental psychology, like Mary Main or James Marcia, a scholar of Erik Erikson, already developed and popularized specific interview techniques in their line of research (on attachment and identity, respectively). Although many developmental researchers use semistructured interviews that often are closer to questionnaires than to a genuinely qualitative approach, a number of qualitative interview variants available have proved fruitful for developmental–psychological research. They range from special interview techniques that support the dialogue between interviewer and interviewees by using elements from the Rogerian psychotherapy approach to more one-sided and open narrative interviews. Specifics of conducting interviews with children have been discussed, for example, by Greene and Hogan (2005).

Written Data

Existing written documents are another form of data that can be used to gain insight into developmental processes. Collecting and analyzing diaries was, for instance, a prominent way to study the emotional life and thoughts of adolescents in early developmental psychology. Likewise, diaries can be used to study processes of transition within the family – for example, through the birth of a child and becoming a mother or father. Contrasting the perspectives of men and women can provide interesting insights. Studying diaries also can serve to investigate processes of coping with critical life events over time, like severe illness or mourning a beloved person. A modern version of this line of research is the study of Internet-based presentations (blogs, social networks, personal websites, or newsgroups – e.g., parentship or in regards to other developmental issues) also referred to as qualitative online research or 'netnography' (Kozinets, 2006). A common procedure in youth and childhood studies is the study of essays produced in the context of school exercises. An interesting aspect in this regard is how the constraints given in this context will contribute to the construction of the data. A final example of written data material used in qualitative developmental research is the completing sentences test – a procedure in which the participants are asked to complete a partial sentence without being given further restrictions.

Group Discussions and Focus Groups

The terms group discussion and focus group often are used interchangeably. Some scholars, however, relate the term group discussion to a more genuine understanding of qualitative research, whereas the term focus group then is used for structured (standardized) discussions with a group of participants (Bohnsack, 2004). Group discussions are of particular use when it comes to analyzing how opinions, attitudes, and orientations emerge, constitute, influence, and modify each other in an exchange of views – in a phrase, when it comes to the genesis of (developmental) processes. As such, they are of particular value for developmental psychology. Possible areas of inquiry are the study of patterns of argumentation with respect to specific ways of reasoning, such as moral dilemmas or social rules.

Furthermore, the focus on discursive, argumentative, and communicative contexts opens up additional possibilities to study negotiation processes in age-homogenous and -heterogeneous groups. Likewise, the study of the meaning of (self) socialization in peer cultures is a particularly prominent example of how group discussions do provide an extraordinary access to developmental processes. Group discussions in general provide an opportunity to investigate the genesis of knowledge. Piaget already had convincingly demonstrated how children's thinking developed after a quarrel took place between children and how during a quarrel or discussion functional moments emerge that initiate the development of self-reflection.

Qualitative Experiments

Qualitative experiments often remain unnoticed in the methodological literature. Disregarding qualitative experiments may be due to the fact that for many the combination of the experiment (believed to be the epitome of nomothetic science) and qualitative research (and its implications and aims) seems impossible.

In developmental psychology it was Piaget who recognized the value of experiments within a qualitative design. With his clinical method, which he understood to be an experimental method in the broader sense, Piaget hoped to counterbalance some of the shortcomings of rigid experimental designs. In a similar vein, Bronfenbrenner (1977) in his harsh criticism of experimental methods with regard to ecological validity pleaded for not using experiments as a verification tool but rather as a heuristic strategy.

Visual Data

The value of nonverbal and visual data and particularly of children's drawings, films, photos, or other artifacts created during play and other mundane activities can be considered as a valuable source for inquiry. Participants, for example, might be invited to photograph their social and physical environments (like kindergarten, school environments, houses for elderly, etc.) and to explore them with techniques interesting for them. In addition to analyzing the product (e.g., photographs, drawings), analysis of the process of producing (e.g., photographing, drawing) allows one to gain insight into the way individuals construct person–environment relations.

Contrary to photographs, videography and observation studies have gained far-reaching acceptance within developmental psychology (starting with the early work by Gesell or

Lewin). To a large extent, these studies draw on standardized designs and statistical analysis. From a qualitative research perspective, such an approach risks ignoring that records produced in such a way capture only reduced fragments of reality that furthermore are restricted to the static perspective of the camera and, in many respects, are inferior to the human capability for sensual and Gestalt perception. This perspective lends to the illusion that video recordings 'capture' reality – an impression that overlooks that they do not relieve from the duty of interpreting what has been 'captured'. A growing number of developmental psychologists, however, use videography and subscribe to the principles of qualitative research. Most of these studies can be found within cultural and discursive developmental psychology as well as in the field of language socialization (e.g., see the Center on the Everyday Lives of Families [CELF and ICELF]).

Participant Observation and Ethnography

Like qualitative research in general, ethnography does not constitute a single set of methods and procedures, but rather it is marked by systematic but flexible deployment of a variety of such methods as participant observation; videography; field notes; questionnaires; and open, semistructured, and focus group interviews (Jessor et al., 1996; see also Camic et al., 2003). An important common characteristic of ethnography is the sustained contact and involvement with a community that allows the researcher to become deeply engaged in the lives and mundane everyday practices of their participants (one difference to the early studies by people like Preyer's or the Stern's is that in this case, the researcher's involvement in the observed situation is reflected). The aim is to understand meaning from the perspective of the local participants within the context of mundane everyday life. It is this aspect that makes ethnography of vital importance for developmental psychology, as it permits a methodically comprehensive approach to studying human development where it actually takes place. Staying in the field, close to the participants (and their interactions), allows for detailed descriptions of different situations over longer periods of time and is an important strategy for collecting longitudinal data and studying processes of transition and change.

Finally, collecting and systematizing extensive field knowledge helps the researcher to generate adequate interpretations and 'thick descriptions' of a particular phenomenon – a term coined programmatically by Clifford Geertz (1973). Particularly with respect to the study of culturally distinct developmental pathways, ethnographic knowledge that only can be obtained through sustained fieldwork and engagement with the participants is indispensable. This might include, for example, knowledge about caregiver's ideas of good child care, their socialization goals, and an understanding of these goals in light of the prevailing sociocultural and sociohistorical living conditions.

Autoethnography

A procedure that has gained increasing attention in recent years with the raise of postmodern thinking in psychology is 'autoethnography' (Ellis, 2004). This approach to research and writing seeks to describe and systematically analyze personal experience in order to understand cultural experience. Methodologically, it combines characteristics of autobiography and ethnography and is an approach to research rather than a specific research method. Through systematic analysis of one's personal experience and by comparing and contrasting this experience against existing research, the researcher aims to identify how personal experience is made possible by being part of a culture or by possessing a particular cultural identity. For developmental psychologists, it offers insights into individual psychological transformation processes across the life span and does so in light of the person's sociocultural embeddedness – for example, the process of becoming a mother, the loss of a beloved person, or coping with illness.

Participatory Action Research

Participatory action research, like ethnography, constitutes a research approach rather than a specific research method and is based on an understanding that research should be conducted not only for but primarily with the people under study (Greene and Hogan, 2005). It commonly is related to the work of Kurt Lewin and has a long tradition within community psychology and social action projects. The outstanding characteristic of action research is its commitment to active, democratic participation, and empowerment of individuals under study as foundation for social change. Procedures range from naturalistic observation to interviews, case studies, surveys, and even experiments. Human psychological functioning is understood to be embedded in and systematically linked to various micro and macro levels of society as postulated in the ecological perspective of Uri Bronfenbrenner (e.g., 1977). This approach has a strong potential for applied developmental psychology, especially for developing intervention programs in many areas and across the life span – for example, to improve the quality of day care centers, youth delinquency prevention programs, preparation programs for parents, family-centered services, and residential homes for elderly. Action research in childhood studies explicitly promotes the participation of children and young people as active researchers to give them a voice and take them seriously as social actors in their own right. Hence, this approach raises the potential for children's self-development and political agency.

Procedures for Data Analyses

Reconstructing subjective experiences and coconstructive meaning-making processes requires adequate and open procedures not only for data assessment but also for data analysis. The material to be analyzed may vary from transcripts derived from interviews or group discussion, essays, observation protocols, diaries, photos, videos, and blogs, to media reports and other collected material. Depending on the specific research question and theoretical background, a number of established procedures are outlined in the following (see also Flick et al., 2004). They can broadly be categorized as coding procedures or and sequential procedures.

Qualitative Content Analysis

Qualitative content analysis is a distinct procedure from quantitative content analysis. This form of analysis is useful for analyzing large amounts of verbal data collected through interviews or focus groups and also offers possibilities for quantification of categories (Schreier, 2012). Its restriction to

a coding manual makes it less appropriate for reconstructing meaning-making processes and for highly open-ended research questions. Thus, it is less suitable for developmental–psychological research that is concerned with the temporal nature of phenomena that need to be reconstructed.

Grounded Theory Methodology

Grounded theory methodology (GTM) is considered to be one of the most popular methods of qualitative research. First formulated within the tradition of the Chicago School of Sociology by Glaser and Strauss and further developed by Strauss and Corbin, it has been developed in a number of ways, leading to a variety of existing versions of GTM (for an overview, see Bryant and Charmaz, 2010). This methodology allows for rigorous and systematic theory development that is grounded in the data. Although GTM envisages an explicit process perspective in its original sociological approach, a procedure elaborated from a genuine developmental–psychological perspective still needs to be developed. Similarly, the paradigm model proposed by Strauss and Corbin as a dynamic conditions-strategies-consequences matrix still needs to be transferred to developmental psychology realms of inquiry.

Interpretative Phenomenological Analysis

Psychological phenomenology recognizes that a whole set of factors leads to differences in people's perception of reality and is committed to the exploration of individual lived experience. Interpretative phenomenological analysis is composed of a series of sets of factors that aim to interpret the accounts of people of their personal lived experience and explicate an underlying structure in these accounts (see Smith and Dunworth, 2003). Its potential for developmental psychology lies in the focus on the subjective experience of individuals and the possibility to study developmental processes in detail and is suitable for longitudinal designs (e.g., identity change during the transition to motherhood).

Discursive Psychology and Discourse Analysis

In line with the recent sociocultural and interactional turn in the field, discourse analysis as developed within discursive psychology (e.g., see Camic et al., 2003; Willig, 2008) constitutes a particularly promising avenue to developmental psychology research. This procedure is oriented to examining social interaction as the site in which psychological phenomena that traditionally have been conceived of as developing inside the mind (attitudes, traits, knowledge, intentions, agency, emotions, identity) emerge in a process of intersubjective agreement. It treats language not as referential, that is, as a means to refer to these phenomena as hidden 'entities' in the isolated mind, but rather as constitutive of social reality and of the mind. Methodologically, it draws on procedures from conversational analysis and applies them to psychological inquiry. It increasingly is used in combination with videography, which allows for paralinguistic features to be included in the analysis. For developmental psychology, it offers possibilities to study early socialization processes in childhood (e.g., in mundane family or peer interactions) as well as locally situated identity construction across the life span (e.g., Bamberg, 2012; for a conversation analytical approach to developmental psychology, see Gardner and Forrester, 2010). Promising fields of discourse in analytical developmental research include the study of Internet-based communication like chats and blogs as they constitute a central arena for social interaction especially in young people's everyday life.

Other forms of discourse analysis also aim at somewhat-different research questions – for example, Foucauldian discourse analysis, critical discourse analysis, or genre analysis (e.g., see Flick et al., 2004; Willig, 2008 for an overview). Their focus is on institutional and social structures that frame specific discursive events and the ways in which ideological and political domination is reproduced in text and talk. Their relevance for developmental psychological research lies in studies concerned with cultural and historical ideologies of various aspects of human development, like childhood, parenting, or aging.

Metaphor Analysis

A more linguistic approach that could be applied fruitfully in future developmental–psychological research is metaphor analysis (Schmitt, 2000). The use of metaphor analysis is obvious in that the term 'development' can be understood as a metaphor itself (although mostly restricted to the path-metaphor; e.g., 'to forge ahead,' 'to stay behind') or can further enter concepts of education (e.g., 'to look after'/'to protect,' 'keep an eye on'). A metaphor analysis offers an exceptional potential for the reconstruction of the description of development from the perspective of the subject, for instance, as a deficit-oriented imagery in such terms as 'age degeneration' or 'loss of functioning' and their important role for understanding aging.

Narrative Psychology and Narrative Analysis

Narrative analysis is concerned with the structure, content, and function of stories in written and oral communication (Bamberg, 2012; Crossley, 2000; see also, Camic et al., 2003; Lyons and Coyle, 2007; Flick et al., 2004). It emerged from the narrative turn in psychology and the seminal work of Jerome Bruner more than 20 years ago. Another early forerunner of narrative analysis can be seen in Nelson's classic case study of a 2-year-old. Analyses of autobiographical life stories provide the opportunity to explicitly address temporality and the individual's reconstruction of developmental processes and are linked closely with the study of narrative identity. Social–constructivist approaches, however, stress the local and situated nature of identity construction and are more concerned with the analysis of 'small stories' in mundane everyday interaction (Bamberg, 2012).

Video Analysis

Video recordings allow one to capture the high complexity of mundane social interaction and accordingly offer a number of possibilities for qualitative analysis, depending on the specific research question and epistemological stance of the researcher (Heath et al., 2010). Videographed data, for instance, can be used partly in interview studies and group discussions as an additional source of information, or as part of larger ethnographic research (e.g., for the study of social interaction in kindergarten, at school, or within the family). Although technological advancements allow for increasingly sophisticated

analysis of video material, transcription of selected portions that will be analyzed in more detail usually is required after a substantive review of the data corpus. The most prominent procedures for qualitative video analysis in developmental psychology are discourse and conversation analysis. Embedded in a longitudinal and ethnographically informed design, it allows microanalytical analysis of change and transformation of interactional patterns over time and, hence, the study of developmental processes.

Performative Social Science

Performative social science refers to the deployment of different forms of artistic performance in the execution of a scientific project (Gergen and Gergen, 2010). Its aim is to offer a social constructionist alternative to traditional empiricist forms of communication in social science, such as theater, dance, fiction, poetry, or multimedia performances. It challenges the assumption that traditional forms of social science writing are the only suitable way to communicate scientific knowledge. Research findings, for example, might be presented in a poetic form or with visual and auditory expositions of data as a new way to disseminate and appropriate scientific research. This procedure strives for an interdisciplinary exchange between science and arts by creating new ways to make findings available and understandable to the participants under study.

Future Directions

The history of qualitative developmental psychology since its beginnings 120 years ago provides us with a variety of examples of how qualitative methods can advance our understanding of human developmental processes. Besides classic procedures like interviews and observations, recent technical advancements have lead to several new forms of collecting and analyzing data. A number of computer programs have been developed specifically for qualitative research (Aquad, Atlas.ti, Dedoose, HyperRESEARCH, MAXQDA, NVivo, QDA Miner, XSight, Qiqqa, Transana). Computer-Assisted Qualitative Data AnalysiS (CAQDAS) allows one to systematically retrieve, organize, and efficiently manage larger data sets and hence to expand the size of the samples. New approaches have emerged from various paradigmatic shifts within the past decades like the narrative turn, discursive turn, interactional and sociocultural turn, and more recently the performative turn embedded within the postmodern turn. Moreover, an increasing interdisciplinary exchange allows for adapting procedures originally developed in different disciplines for the specific demands of the field. In the twenty-first century, qualitative research in developmental psychology is a flourishing field that can be applied to studies of emotional, cognitive, social, and language development across all age-groups, developmental contexts, and cultural milieus.

Recent textbooks of developmental psychology not only acknowledge qualitative methods but also dedicate whole chapters to the topic (e.g., Smith and Dunworth, 2003). But have these methods really arrived in developmental psychology? Indeed, in a 1999 roundtable discussion, nearly two-thirds of editors of English-language mental health and child development journals argued in favor of publishing more empirical qualitative studies to, as they emphasized, initiate a necessary shift in this area of research (see Mey, 2010). Conversely, some of the most important mainstream journals in the field persist in opposing publication of genuinely qualitative research. Although interest has been increasing in mixed-method designs in the past years, the qualitative part of such designs often consists of open procedures rather than genuinely qualitative methods that are used within a quantitative paradigm. A systematic integration of genuinely qualitative and quantitative research designs seems to be difficult in light of the distinct epistemological underpinnings. If, however, we take one of the central criteria for the any empirical study seriously – the adequacy of the method for the phenomena under study – then the decision for or against specific methods needs to be derived from the research questions and the object of investigation, respectively. Newer methodological developments provide a number of opportunities to help the field study what it aims to study – that is, processes of change with age in the psychological functioning of individuals – in a systematic and more effective way. An adequately reflected methodological pluralism in light of the nature of human development as embedded in mundane everyday interaction and meaning-making processes within culturally prestructured patterns of society constitutes a promising avenue to advance the field.

Abstract

The history of qualitative methodological practices concerns development of research practices, objects of inquiry, and analytic strategies in relation to archival, observational, and interview data. There are three unevenly autonomous and connected streams: (1) historical inquiry and historical social science (especially historical sociology), (2) ethnographic research in anthropology, and (3) social science methodologies of interviewing and field research. Despite the diverse domains, qualitative methods have often converged in shared analytic issues, logics of comparison, and epistemological issues. Recently, qualitative methods have been pushed in two contradictory directions: toward increasingly powerful logical formalization and toward 'postmodern' emphasis on historicity and reflexivity.

This brief history traces the development of sociohistorical methodologies employed in relation to data that are either archival or based on direct social observation and interaction, insofar as these methods do not depend on quantitative analysis. The history of qualitative methodologies involves three unevenly autonomous and connected streams: (1) historical inquiry and historical social science (especially historical sociology), (2) ethnographic research in anthropology, and (3) social science methodologies of interviewing and field research. Despite the diverse domains and their differentiation, qualitative methods have often converged in shared analytic issues, for example, the relation between qualitative data and social theories and concepts, logics of comparison, epistemological issues concerning objectivity versus relativism, and questions of analytic methods of deduction versus induction. These developments can be explored in three respects: (1) institutionalization, (2) how objects of inquiry have been construed, and (3) logics and analytic strategies. Recently, debates in the wake of the 'postmodern' turn have created new possibilities for understanding qualitative research, and research more broadly, as a terrain of interdiscursive communication with properties of 'integrated disparity.'

Institutional Emergences of Qualitative Methods

Sociohistorical inquiry emerged long before the rise of the modern academic disciplines. In China, statecraft early on was informed by typologies of social circumstances and transitional possibilities of action specified by the *I Ching*. In the fifth century before the modern era, the ancient Greek Herodotus wrote as much as an observer of the contemporary as a historian. And during the fourteenth century, in the Arab world, Ibn Khaldun wrote in a way that anticipated comparative and historical sociology. These and other relatively sophisticated practices of inquiry coexisted with much more basic efforts of social groups to document their existences through the development of archives, king lists, annals, and chronicles. Thus, the arrangements through which sociohistorical knowledge has been produced are long-standing and diverse.

However, contemporary qualitative inquiry is especially a product of modernity, and of critical and postmodern reactions to the research practices spawned of modernity. Initially, qualitative research was inextricably linked with the gradual emergence of modern national societies and their colonial expansion, most concertedly during the nineteenth and twentieth centuries (Vermeulan and Roldán, 1995). Intellectually, the rise of social and humanistic disciplines can be traced to the European Enlightenment of the eighteenth century. Eighteenth-century thinkers such as Giambattista Vico and Johann Gottfried Herder increasingly began to characterize social and historical processes as subject to understanding in their own terms rather than as products of the will of God alone, and Edward Gibbon developed analytic history by use of concrete social explanations (i.e., in his *Decline and Fall of the Roman Empire*).

In the nineteenth century, history developed under two aligned tendencies: (1) efforts to differentiate the professional discipline from popular historical writing and (2) attempts to harness sociohistorical inquiry to the 'liberal' project of constituting the State, citizens, and the economy as a viable assemblage for social development. Thus, Leopold von Ranke sought to establish accounts of 'what really happened' on the basis of 'scientific' validation of facts drawn from archival sources, while simultaneously positing the history of political and religious elites as the subject matter that would reveal the meaning of history as a whole, that is, as a manifestation of the will of God. Historians in the United States for the most part embraced a modernist quest for 'objectivity' inspired by Ranke (Novick, 1988), while leaving the ideological and theological underpinnings of Ranke's scientific historicism largely uninspected. By contrast, the exemplary efforts of Max Weber to offer an alternative notwithstanding, historical sociology developed through the middle of the twentieth century mostly in relation to grand evolutionary social theories, at points aligned with anthropological ethnology, which was focused on constructing racialized world evolutionary sequences of social group development. Only after World War II, and especially in the 1960s, did historical sociology develop a methodologically sophisticated array of comparative and theoretical strategies for the analysis of history (Barnes, 1948; Smith, 1991).

As for field research, it emerged in relation to modern colonial expansion and capitalist industrial development. Among Europeans, especially from the sixteenth century

 http://dx.doi.org/10.1016/B978-0-08-097086-8.44044-4

onward, knowledge gained from travel became a basis of colonial power sustained by exploratory expeditions, practical sciences, missionary work, and territorial penetration of colonial civil services. Sometimes authors combined traveling for a trading company or state with writing for a popular audience that wished to visit other lands vicariously. But epistemological principles of social knowledge were also at stake. Samuel Johnson's later eighteenth-century trip to western Scotland implicitly demonstrated that cultural differences would require forms of knowledge different from the then emerging rationalized social quantification (Poovey, 1998).

'Exploration' journals became increasingly systematic not only in describing the flora and fauna of the 'discovered' world but also in inventorying the languages and practices of non-Western peoples. Organizations such as the Smithsonian Institute (founded in 1846) coordinated efforts to gather data and circulated inventory questionnaires that could be filled out by nonprofessional travelers. Yet travelers' accounts – often saturated with racist and ethnocentric assumptions – largely served as grist for evolutionary ethnology and philosophical ('armchair') anthropology, for example, in Emile Durkheim's work on religion and James Frazer's *The Golden Bough*.

By the late nineteenth century, ethnology and philosophical anthropology still dominated the disciplinary space where modern ethnography was beginning to emerge. Lewis Henry Morgan's field study of the Iroquois, published in 1851, was largely a springboard to his ethnology. Only with the work of Franz Boas and Bronislaw Malinowski did inquiry begin to abandon the ethnological search for transgroup anthropological principles of development and emphasize analysis of social groups in their contemporaneous existences (a shift much bemoaned by the theorists). Boas was a crucial transitional figure. He initially intended his late-nineteenth-century observation and interviewing of indigenous peoples such as the Kwakiutl to advance his studies of perception and speech, to the point that he sometimes became impatient with ceremonial potlatches that wasted research time! Nevertheless, Boas pioneered efforts to create valid information based on direct, systematic field research, and he trained students such as Edward Sapir and Margaret Mead.

During and after World War I, Malinowski even more strongly embraced sustained participant observation oriented toward characterizing a group's present way of life. His Trobriand Islands fieldwork, published as *Argonauts of the Western Pacific*, proposed a methodology borrowed from sociology, placing empirical observations within a functionalist framework, yet it also consolidated the modern ethnographic role as that of the expert offering an authoritative account aimed at an emic understanding of the 'other's' point of view. This tension between an objective theoretical framework and emic analysis became a hallmark of modern anthropology, for example, in the French Durkheimian tradition, carried forward by Claude Lévi-Strauss (and in Britain by Alfred R. Radcliffe-Brown), and even in the way Clifford Geertz sometimes combined 'thick description' with social systems rhetoric.

Ethnographic study of the exotic 'other' was hardly the only impetus to institutionalization of field research. Famously, Alexis de Tocqueville voyaged to the United States in the 1830s to learn more about the American prison system. During the late nineteenth and early twentieth centuries, sociology was influenced by similar practical filed observational quests for knowledge about social conditions, for example, in studies of social issues sponsored by the *Verein für Socialpolitik* in Germany, by socialists in England, and among social workers such as those at Chicago's Hull House in the United States.

Building on the Hull House tradition, during the early twentieth century, sociology's strongest institutional development of qualitative methodology came at the 'Chicago school' founded by Robert Park, who took inspiration from Boas and Malinowski to encourage field research (DeVault, 2007). The city of Chicago became an urban laboratory for the direct observational study of social phenomena. Chicago faculty and students produced a stream of monographs such as *The Hobo* (1923) and *The Gold Coast and the Slum* (1929), and their approach found common cause with observational and in-depth interviewing field studies of communities, such as *Middletown* (1929) and the *Yankee City* studies (1941–59), work influenced by anthropological ethnographies (and sometimes carried out by anthropologists).

Beginning in the 1930s, American sociology underwent a broad disciplinary shift toward positivism (Steinmetz, 2007), the increasingly hegemonic position of which shaped the context in which qualitative field researchers operated. Only toward the end of the twentieth century did major positivist and quantitatively oriented departments such as the University of Wisconsin begin to reaffirm the importance of qualitative methods. However, that development occurred precisely because qualitative researchers maintained and developed diverse enterprises during the later half of the twentieth century. In the 1950s, Herbert Hyman formalized interviewing as a methodology, and Chicago students such as Howard S. Becker, Jr, took up the pragmatic and symbolic interactionist Chicago tradition that had been initiated by George Herbert Mead and developed by Everett Hughes. During the 1960s, phenomenological sociology, inspired by Alfred Schutz, and ethnomethodology, promoted by Harold Garfinkel, emerged as alternative approaches that problematized objectivity, realism, and the social activities through which qualitative knowledge is created. Added to this mix during the same decade were the constructivism of Peter Berger and Thomas Luckmann, the dramaturgical approach of Erving Goffman (himself trained at Chicago), and a nascent bridge between field research and history via the emerging interest in oral history. These developments, together with the 1960s retooling of sociohistorical inquiry at the hands of scholars such as Reinhard Bendix, E.P. Thompson, and Barrington Moore, set the stage for an efflorescence of qualitative research in the last decades of the twentieth century.

Yet, just when qualitative research flourished, it also underwent differentiation, along with sometimes fruitful methodological crisis. Some symbolic interactionists, ethnomethodologists, and comparative and historical sociologists sought to affirm the scientific legitimacy of their enterprises and gain acceptance among wider audiences by formalizing research methods and strategies, while other researchers took seriously the rejection of scientism consolidated from the 1960s onward by critical theorists such as Jürgen Habermas, hermeneuticists such as Paul Ricoeur and Charles Taylor, philosophers of history (most notably Hayden White), feminist epistemologists such as Dorothy Smith and Sandra

Harding, anthropologists like Marshall Sahlins and James Clifford, and the wave of poststructuralist and postmodern 'turns' heralded by Michel Foucault and Jacques Derrida. Some ethnographers became reflexive to the point of envisioning research itself as performative or eschewing study of any 'other' in favor of autoethnography. Ethical considerations about privacy, asymmetry of field research, and exploitation of subjects – raised especially by feminists and within anthropology – cast long shadows on the high modernist quest for objectivity and validity in qualitative analysis (for discussions of a variety of such issues, see Denzin and Giardina, 2007). During the past two decades of the century, these developments, along with the rise of world-systems and globalization theories, led to the formulation of new hybrid qualitative methodologies by such researchers as Michael Burawoy and Philip McMichael that linked the local and the global, ethnographic and historical analysis. The old dream of the ethnologists, of theorizing case studies in relation to general social processes, was reborn, but in a dispensation that rejected ethnological ethnocentrism. On a different front, historical and comparative sociologists have continued to reflect on their own recent history and how they might connect more effectively both with substantive topoi of sociology and with social theory (for a set of pivotal essays, see Adams et al., 2005). In general, then, research using qualitative methodologies has become strongly institutionalized within the social sciences, yet methodological practices and relationships with disciplines remain very much in flux.

The Object of Inquiry, a Brief History

One enduring problem of qualitative research concerns how to construe the object of inquiry, that is, what is studied. At the end of the eighteenth century, Immanuel Kant raised the philosophical problem of selection, namely, which of myriad events revealed the 'guiding thread' of history. In the nineteenth century, under the influence of teleologies such as those of Hegel and Ranke, historians were generally content to regard their studies as centered on 'natural' objects that had their own coherences in the world itself. However, as Hayden White (1973) has shown, the nineteenth-century European historians established rhetorical coherence through one or another genre of emplotment that offered a metanarratological structure into which to fit events. The alternative possibility, which developed outside of history (and increasingly within it), was to constitute the object of analysis via theory. Thus, Karl Marx and Frederick Engels theorized about capitalism as a dynamic totality changing through its own contradictions over time, and they used their perspective to thematize social events and processes in places as diverse as India, the United States, and Manchester, England. Within academia, the Marxian approach found its counterpart in the later nineteenth-century program of German historian Karl Lamprecht, who sought to displace Ranke's elites as the object of historical analysis with the study of diverse social groups and their interaction.

The Kantian problem of the relation between object and selection was more directly addressed during the German *Methodenstreit* toward the end of the nineteenth century, especially through the effort of Wilhelm Rickert to posit the objective value of truth in a way that would yield a shared way of looking at the world, and by extension, a shared object. Among mainstream historians during the twentieth century, a sort of ontological historicism emerged, in which shifts in styles (e.g., the emergence of social history) depended on shifting the object of historical analysis, rather than its methods. The major alternative to historicism, which Max Weber spelled out at the beginning of the twentieth century, depended on two central assertions:

1. that because values cannot be warranted scientifically, the objects of sociohistorical inquiry cannot be scientifically determined, even though, once objects are determined, scientific methods can be applied to their study; and
2. that the objects of sociohistorical inquiry are not natural kinds, but rather, infinitely varying sociohistorical phenomena that become objects of inquiry through cultural interest in them.

Alternatives to Weber's approach can be traced in history to the Annales School and Marxism, and in the social sciences, methodologically to the objectivism of Emile Durkheim, and analytically to Georg Simmel. Durkheim had provided the general warrant for objectivist approaches in his 1895 *Rules of Sociological Method*. And, in a way that is not widely recognized, Durkheim's structuralism had its equivalent in Simmel's early-twentieth-century identification of social 'forms' (such as 'sociability'), a central inspiration for a number of qualitative symbolic interactionists (Hall, 1999: Chapter 4). Within structural Marxism, the perspective of the proletariat was assumed to offer an objective standpoint for the analysis of capitalism, although during the first half of the twentieth century, this position was rendered problematic by the scholarship of Georg Lukács and critical theorists Max Horkheimer and Theodor Adorno. If the object of inquiry for structuralist Marxism was a totality, for the Annales School, in the formulation of Fernand Braudel, the totality was the grid of objective temporality, onto which multiple levels of change – ecological, structural, *histoire évènmentielle* – could all be mapped (Hall, 1980; Burke, 1990).

Ethnographic field researchers during the first half of the twentieth century generally treated their cases as naturally occurring 'primitive' societies subject to 'salvage anthropology.' Yet, asserting the supposed isolation of the natural case became increasingly untenable with the post-World War II emergence of first modernization and then world-systems-theory-approaches, both of which drew into question the autonomy of indigenous social groups. A parallel tension developed within sociological domains of field research. At the moment of high modernism, symbolic interactionists like Herbert Blumer would posit the empirical world 'out there' as the object of 'naturalistic research.' Yet, interactionists shared with phenomenologically oriented researchers and ethnomethodologists the sense that the empirical object of research was 'constructed,' that is, that the meaningful world was constituted by its participants' practices, which logically would include researchers themselves.

In the early twenty-first century, the objectivist–relativist divide in constituting objects of qualitative inquiry persisted, but the cultural and Foucauldian turns in history, the linguistic

turn in anthropology, increased understanding of how ethical and personal safety choices shape data from field research, and the challenges of analyzing social phenomena in relation to the internet all created conditions in which answers to the questions of how research is to be framed and 'what is a case?' had become considerably more nuanced and sophisticated (on the latter issue, see, e.g., essays in Ragin and Becker, 1992). In particular, by 1978, Arthur Stinchcombe argued against comparing cases as total entities one against another, and in favor of searching out the deeply analogous social processes that might be at work in cases that, on the face of it, might not even be considered as members of the same set. In a different vein, George Marcus has tracked the shift in anthropology from the deep study of a delimited ethnographic site to more integrated analyses of developments across disparate venues.

Overall, in today's postpositivist climate, reflexivity rules. Even objectivists and realists increasingly recognize that theoretical orientations and concepts have consequences for how cases are construed, while dialogic relativists, some of whom doubt the existence of any straightforwardly accessible empirical world to be studied, have had to come to grips with the problem of how adequately to 'represent' the (constructed) realities of their encounters with the people about whom they write.

Developments in Logics and Methodologies of Qualitative Analysis

Philosophers have debated the logics of human reasoning for millennia. But the most compelling specification directly relevant to modern sociohistorical inquiry came in John Stuart Mill's 1843 philosophy of scientific method, which specified two methods of nonexperimental research. The method of agreement entailed isolating crucial similarities in a set of diverse cases, yielding the claim that if two aspects co-occur under otherwise diverse circumstances, they are likely to be somehow connected with each other. On the other hand, the indirect method of difference extended the logic of control group experiments to nonexperimental settings, by searching for contingent corelated variations. In effect, two (or more) findings derived from parallel uses of the method of agreement could be placed side by side. If a particular propensity were found only in the presence of another particular propensity, and never when the second propensity was absent, Mill reasoned that one was "the effect, or the cause, or an indispensable part of the cause" of the other.

The application of Mill's logic to sociohistorical inquiry met with opposing visions of qualitative analysis that became crystallized by issues raised during the late-nineteenth-century *Methodenstreit*. Whereas the logic advanced by Mill yielded a nomothetic search for general principles, an alternative, idiographic view suggested that the study of human affairs necessarily dictates emphasis on the individually distinctive, indeed unique, aspects of social phenomena. Whatever the resolution to this question, a second issue concerned whether the special character of sociohistorical phenomena made them necessarily the subjects of a different kind of knowledge than the explanatory search for universal causal laws, namely, a cultural science based on understanding social meanings and actions. Three broad logics of qualitative methodology – interpretive strategies, ideal-type analysis, and formal analysis – can be traced in relation to these contestations.

First, early in the twentieth century, Wilhelm Dilthey proposed a historicist hermeneutics that would seek to understand history as embedded in the life meanings of the people who participate in it. This basic approach has its parallels in both ethnography and sociological field research. Elaborations of analytic logics were especially concentrated in sociology. In the 1940s, Alfred R. Lindesmith developed the method of 'analytic induction' as a procedure for successively refining hypotheses in relation to cycles of field research, an approach that Barney Glaser and Anselm Strauss subsequently reinterpreted as 'grounded theory.' And in the 1950s, a now-classic essay by Howard S. Becker reflected on 'problems of inference and proof' in the analysis of the substantial amounts of field notes and other documents. By the 1960s, 'participant observation' (Platt, 1983) and in-depth interviewing became increasingly institutionalized as legitimate approaches to inquiry, with their own epistemological rationales, challenges (notably how to construe and know subjectivity of the other person), research procedures, and handbooks, such as those of Buford Junker, Severyn Bruyn, and John Lofland and Lyn Lofland. Ultimately, epistemologically, as Isaac A. Reed (2011) demonstrated, the broadly interpretivist logic at the heart of much qualitative research has become a fruitful basis by which to probe the deep cultural structures of both positivist and realist approaches to inquiry.

Second, working at the same time as Dilthey, Max Weber consolidated a *Verstehende* approach that was both comparative and interpretive. He did not deny the possibility that sociohistorical inquiry might discover general regularities of the sort Mill sought to identify, but he regarded individualizing knowledge as the central value interest of sociohistorical inquiry. Therefore, he combined explanation and understanding, by using generalized ideal types that would be 'adequate on the level of meaning' and thus serve as meaningfully coherent analogs to the patterned character of empirical cases, yet, nevertheless, allow for comparison beyond individual particularities. Weber's methodology became central to the renaissance of historical sociology consolidated in the 1960s. In the 1990s, Geoffrey Hawthorn and David William Cohen, among others, developed Weber's logic of the 'mental experiment' into 'counterfactual analysis.'

Third, Mill's methodological effort became the touchstone for subsequent formalizations of qualitative logic. The most important elaboration has been the Qualitative Comparative Analysis pioneered by Charles Ragin, which builds on Mill's principles by using set theory and Boolean algebra to identify multiple configurational patterns within an array of systematically described cases.

In different lines of development, with the late twentieth century turn toward narrative and the study of discourse (partly inspired both by ethnomethodology and poststructuralism), scholars such as Larry Griffin theorized ways in which narrative accounts might become subjected to formal analysis that would yield descriptions of discrete social processes. And researchers more generally have begun to use one or another of various software programs for organizing and analyzing qualitative data – for example, Atlas.ti, Ethno, and NVivo. These

and related developments of formalization – as well as techniques of 'triangulation' that compared findings gained from diverse methodologies and the use of mixed and multiple methods more generally – increasingly blurred the lines dividing qualitative from quantitative analysis. With logical development, powerful new analytic techniques, and mixed methods came increased acceptance of qualitative research, but also critique. Three major recent developments stand out.

First, Stanley Lieberson (in Ragin and Becker, 1992) questioned whether formalization alone could resolve logical difficulties of comparative studies with small numbers of cases. For qualitative researchers, however, his critique may not be so devastating as would seem at first blush, because nested and intersecting comparisons and rich uses of data can be used to safeguard against the narrow errors of logic that Lieberson so effectively documented.

Second, a more convoluted set of issues arose a decade later in a review symposium in the *American Journal of Sociology*, where Loïc Wacquant (2002) critiqued the methodologies and logics of three widely read urban ethnographies – by Mitch Duneier, Elijah Anderson, and Katherine Newman. Responding in the symposium, the authors discussed by Wacquant characterized his readings of their work as tendentious and ideologically driven. The manifold (and often riveting) challenges and disagreements in this exchange are less important for general issues of qualitative methodology than the often shared bases of critique. Notably, all participants in the symposium treated morals, values, and ideology as both insidious in their capacity to underwrite reductionist metanarratives and important to understand – both in the subjects and reflexively – in the practices of research. The most serious methodological divides among symposium participants concern: (1) what credence should be extended to subjects' accounts versus explanation in relation to wider social contexts – revisiting a long-standing anthropological debate over emic versus etic ethnography; (2) whether to embrace theoretically driven or more grounded research (the latter position especially strongly defended by Anderson); and (3) whether, in order to enhance validity, the subjects of research ought to be guaranteed anonymity or, with their permission, have their identities revealed – and relatedly – offered the opportunity to read a researcher's accounts about them (practices championed by Duneier in both his book *Sidewalk* and his response to Wacquant). The symposium's *frisson* shows that enduring issues in qualitative methodology remain unresolved, and subject to alternative conventional resolutions. Thus, in relation to Dunieir's use of real names, although historians would not think twice about doing so in their studies, a sociologist criticized such a practice in a review of the author's 1987 sociological history of Jim Jones, *Peoples Temple*, and the 1978 mass suicide at Jonestown. On a different front, the divide between grounded and theoretically driven approaches is firmly ensconced in enduring alternative styles and logics of social inquiry.

Third, in *Reinventing Evidence in Social Inquiry: Decoding Facts and Variables* and in a symposium on 'Varieties of evidence and method in cultural sociology' (Berezin, 2014), Richard Biernacki (2012) strongly criticizes research practices that code texts in relation to observer's categories. A number of approaches to content analysis used in qualitative research, he argues, efface meaning and yield analytically incoherent results. Biernacki's critique does not resolve the status of measurement in relation to meaning, but it sounds an alarm about an issue that qualitative researchers need to give serious attention.

The developments in logics and methodologies of qualitative analysis over the long term have not settled fundamental issues. However, they have brought increased sophistication to the practice of qualitative research. Moreover, they have increasingly raised issues of wider importance. Specifically, the Millsian logic of comparison, the relation between values and knowledge production, meaning and the problem of measurement, how to construe the character of theoretical concepts in relation to variables, cases, and social phenomena are issues that *quantitative* methodologists took very seriously some decades ago. But more recently, their focus has been more on improvement of statistical techniques. Because *qualitative* methodologists in recent decades have sought to confront these issues, their efforts now bear a salience for methodology more generally.

Postmodern Reflexivity in the Shared Domain of Qualitative Methods

By the end of the twentieth century, there had been substantial differentiation and development of qualitative methods, as well as experimentation in both research role relationships in field research and the form and rhetoric of texts reporting qualitative research more generally. Yet, these methodological shifts typically transpired within relatively autonomous schools where one or another approach was alternatively embraced, reinvented under a new flag, or syncretically revised in relation to alternatives. The differences between inductive and deductive historical sociologists, like those between mainstream symbolic interactionist field researchers and those who had taken the postmodern turn, often loomed as important as the disjuncture between quantitative and qualitative research more generally.

Under these conditions, a fruitful development has been the specification of typologies that describe alternative practices of inquiry in terms of the shared or contrasting cultural logics of their research methods, rather than assuming an equivalence between particular qualitative methodologies and various schools or genres (e.g., symbolic interactionism, cultural history). Theda Skocpol and Margaret Somers, and Charles Tilly developed typologies of historical and comparative sociology, and John R. Hall (1999) used discursive analysis to elaborate a general typology describing eight core cultural logics of research practice. In these terms, the three methodologies most favored in field research and historical sociology are historicism, contrast-oriented comparison, and analytic generalization. However, beyond these methodologies is a wider array of possibilities, including practices such as 'configurational history' that are often employed without benefit of formalization, and other practices, such as 'universal history,' that persist despite postmodern condemnation of 'metanarratives.' Typologies of qualitative analysis might seem to harden the boundaries between alternatives. However, the outcome of discursive analysis is the opposite, for it reveals

a condition of 'integrated disparity' among research practices that share cultural logics in ways not previously understood, and it clarifies the conditions and potential for translation of research knowledge produced through radically alternative research practices (Hall, 1999: Chapter 9). Thus, although qualitative research is shot through with contemporary tensions between positivism, realism, relativism, and constructivism, qualitative researchers may find that general recognition of sociohistorical inquiry as a reflexive enterprise will create ripe conditions for a new era of sophistication about qualitative research, with implications for research practices more widely. But to consider those possibilities moves beyond history into the realm of as-yet contingent possibility.

Qualitative Methods in Geography

Abstract

Qualitative methodology is employed in human geography in a variety of ways, reflecting different topics, theoretical questions and philosophical approaches. This article traces the use of qualitative methods over time in the discipline, identifying key intellectual turns and ethical concerns that have influenced how and why particular methods are employed. Continued methodological innovation is observed as geographers explore the complex interconnectedness of human action, space and place.

Contemporary human geography is characterized by wide-ranging topic areas and theoretical discussion, accompanied by methodological plurality. A central concern with spatiality is constant, but a diversity of geographical imaginations (Gregory, 1994) is reflected in a continuing exploration of methodological approaches that may be used to investigate how 'geography matters' in the unfolding of social, economic, and political life. Among these, qualitative methodology provides an alternative paradigm of knowledge creation to that of quantitative techniques. With its admission of subjective experience and focus on meaning, qualitative methodology provides a variety of ways through which to analyze and interpret landscape, region, location, space, place, and the complex intersections of social and spatial relations. It has been critical to the ongoing reimagining of the discipline as shifting philosophical and theoretical debates are integrated into empirical inquiry.

A Paradigm of Inquiry and Collection of Methods

Rather than accepting the possibility of a unitary, objective explanation of observed phenomena, qualitative research approaches acknowledge and seek the multiple and partial versions of reality that are constituted in the course of social life. Embracing a variety of approaches and field methods, a common interest in qualitative research is to enhance understanding through description and concepts grounded in the perspective of those studied. The meanings brought to bear by individuals and groups in ordering and making sense of their everyday social life and its spatiality are privileged in analysis. Methods of inquiry include various ethnographic approaches, including participation in and observation of the worlds of those studied and nonstandardized forms of interviewing with individuals or groups; text and visual analysis; and a growing repertoire of other nonnumerical ways of observing, describing, and interpreting the world.

The shifting understandings of relationships between people and places and society and space are important in circumscribing how specific qualitative research strategies are employed. Interest in epistemological issues, particularly through the critical arm of the discipline, has fostered debate about the production of geographical knowledge and further shaped the choice of methods. There are close associations among theoretical developments, philosophies underlying inquiry, societal change, and the now well-established use of qualitative methods in geography. Such methods are used in various ways according to the questions and purpose of research seeking to understand complex sociospatial relations from different subdisciplinary and theoretical perspectives. They can provide descriptive data in mixed strategy designs to enhance findings from quantitative data, but more commonly are associated with postpositivist analyses that center the interpretation of meanings in explanation of narrative and visual data. Inductive analyses of narrative data, informed by theory, focus on generating concepts grounded in categories emerging from the data. Interpretation of various types of visual data, such as paintings, films, photographs, maps, and historical documents, similarly are sensitized by the theoretical and philosophical lenses of the 'reader.'

Qualitative Methodology in a Context of Philosophical and Theoretical Turns

Following the dominance of quantitative methods in the 1960s, intellectual turns have brought new questions and new topics to the agenda of geographical inquiry, together with a rethinking of appropriate methods. Geographers from a number of subdisciplines have explored qualitative approaches in their research as the respective influences of humanism, postmodernism, feminist scholarship, cultural studies, a new material turn, and an interest in emotional geographies have problematized conventional methods of inquiry and categories of analysis.

Humanistic geography, with its philosophical inspirations from idealism, phenomenology, and existentialism, first challenged the strong quantitative turn of the 1960s (Ley and Samuels, 1978). Interest in human agency, the inclusion of people's intentionality, a focus on lived experience, and the quest of understanding how meanings were produced in the context of interacting social and geographical worlds marked the value of qualitative research strategies. Participant observation studies produced ethnographic accounts that permitted a linking of the social with the geographical in ways that opened up inquiry to numerous topic areas that privileged the perspective of the human subject. Interpretation of landscapes included concerns with sense of place, while

case study approaches informed by a theoretical framework of social constructionism explored the embeddedness of human action and perceptions in place and provided models of inquiry for the 1980s. The qualitative methods text of Eyles and Smith (1988) signaled the establishment of qualitative research as an appropriate and useful paradigm of knowledge production within the discipline of geography.

Paralleling these developments, the influence of feminist scholarship resulted in further embracing of qualitative strategies in research. Noting the absence of women in geographical representations of the world, feminist geographers set out to include the neglected 'half' of the population in the mappings and narratives of the discipline. In making the lives and geographies of women visible, qualitative methods, as in other disciplines, were privileged in their ability to uncover the everyday lives of women and the spatialities of their domestic and paid work (McDowell, 1992). Bringing subjective realities of women into geographical explanation exposed the masculinist partiality of geographical inquiry and permitted the construction of concepts reflecting the geographies of women's lives. Linking principles of research with an emancipatory aim, qualitative approaches remain important in feminist methodology as a vehicle, together with the contribution of quantitative methods, in exploring the spatiality of gendered social relations (see Jones et al., 1997 for an example).

Postmodernism, the ongoing development of feminist theorizing and the later influence of cultural studies brought a 'cultural turn' to human geography (Massey et al., 1999). The importance of discourse in constructing human subjectivity and representing difference, whether reflected in the organization of space, social life, or in visual representations, was an important aspect of a complex literature on culture that influenced methodological approaches. Throughout human geography, qualitative methods enabled inquiry to reveal the lifeworlds of marginalized 'others,' to engage critically with various media as cultural representations, to expose the multiple, partial meanings of landscapes and texts, and to disrupt many taken-for-granted categories of analysis. Immigrants, the ill, the disabled, the colonized, children, the aged, and other groups on the margins of earlier inquiry emerge as 'others' whose subjectivities, emotions, and material geographies are included in a broadened geographical knowledge. Ethnographies of workplaces and interviews with elites, analysis of contemporary visual representations of social diversity, and the inclusion of historical texts that include women's experiential accounts are examples that further reflect a concern with competing knowledge and representations of the world. These journeys into the lives of others have led to an expansion and innovation in field techniques, including the use of life stories, focus groups, autobiographical writing, photography, film, and the adaptation of interviewing techniques and formats to meet the needs of particular research projects.

Constructing Knowledge through Qualitative Research: Methodological Issues

In tandem with the use of qualitative research strategies, geographers have engaged with a methodological literature in the social sciences discussing the difficulties that emerge when conducting research with the 'other' of studies. Reflection centers on the complexity of constructing knowledge through reliance on the intersubjective relationship between researcher and researched and the interpretation of data through the self as a socially positioned researcher who is part of the world under study. Issues of rigor in research design and practice have been addressed with attempts made to translate the concepts of quantitative research into those more amenable to qualitative methodology, but most discussion has focused on the close association between practical and theoretical dilemmas in research, and their location in epistemological concerns.

The particular attentiveness of feminist scholars to the micropolitics of research encounters, together with the acknowledgment of the situatedness and partiality of all experience and knowledge, have become the concerns of many qualitative researchers in the discipline. Gaining access to previously subjugated knowledge is shown to be a process located within a layering of power-laden social relations that situate the face-to-face research encounter within the wider politics and processes of 'the field,' theoretical and philosophical tensions, and the institutional values and processes of universities and funding bodies. Specificity of place is shown to mediate how this intricate layering plays out in the microdynamics of particular fieldwork situations.

Particular issues vary in different types of inquiry, but the exercise of reflexivity by researchers has problematized the whole enterprise of knowledge production. Whether in the context of reading landscape as text, rewriting colonial geographies, the demedicalization of medical geography, the shifting concerns of feminist inquiry, interviewing elites in economic geography, or exposing processes of exclusion of marginalized groups in society, researchers consider the different ways their own identities and contextuality influence their analyses.

That the findings of research are theory laden and interpreted through the researcher's subjectivity have brought attention to the presentation and writing up of research. The representation of the multiple voices of the researched is seen as a politically charged and theoretically tricky enterprise. Both in relation to narrative and visual data interpretation, the text produced and its claims to knowledge are problematized. The authority of the author is challenged, in that a particular representation is one of several possibilities. Following from this, the reading and consumption of research writing are viewed as crucial dimensions of the research process and the development of knowledge, rather than separate activities.

Attempts to disrupt hierarchical research relations, including issues concerning the politics and ethics of qualitative research, have remained at center stage in methodological debate. For whom research is conducted, how findings are used and related to theory production, and concern over the possible exploitative nature of the relationship with research participants are important considerations in research conduct. Exploration of participatory and emancipatory models of research, with different forms of collaboration between 'the researched' and 'researcher' reflect a thinking through how academia and activism may be effectively connected (Cahill, 2007; Sharp, 2005). The ethical issues involved in such attempts to 'empower' are a necessary and important focus of discussion. Visual methodology is attracting considerable

attention as the potential of visual methods in data collection are examined, whether in the form of photoelicitation interviewing, participatory video, or film (see, for example, Garrett, 2011; Oldrup and Carstensen, 2012; Ortega-Alcázar and Dyck, 2012; Rose, 2012). The connection made between visual methodology and social action, and the potential of different types of visual methods to level out power relations in research, make innovative use of the visual in research particularly appealing to those working with children, youth, and more vulnerable groups in society. In addition, research output in the form of film or photo-exhibition creates an accessible platform for discussion of research findings across a variety of audiences outside the conventional output of written scholarship.

Continuing Contributions

Expansion of the use of qualitative methods in geography is reflected in special issues of geographical journals and new texts on research methods that focus on qualitative methods or include qualitative approaches as important, rather than subordinate research strategies (Davies and Dwyer, 2007, 2008; DeLyser et al., 2010; Dwyer and Davies, 2010; Hay, 2012). Their value is recognized as theoretical developments have signaled the need to find new ways to discover and analyze data appropriate to current topics and questions. The various methods of qualitative research have opened up different ways of 'reading' and 'seeing' landscape, space, place, and the relationships between people and environments, so continually reshaping the nature and scope of geographical inquiry. The ongoing theorization of space, which has emphasized its relational, social, and recursive dimensions, has been accompanied by qualitative studies that are inclusive of human experience, perceptions, and meaning. Such studies have brought into view the diversity of local, everyday geographies, while at the same time locating individual and group experience within complexly linked local, national, and global relations.

The use of qualitative and quantitative methods is sometimes presented in terms of competing paradigms, sitting uncomfortably with each other. Theoretical turns and epistemological concerns may suggest that one be privileged over the other in the quest for valid knowledge in geographical inquiry, but different questions require different approaches. Both quantitative and qualitative works can and do contribute to furthering the understanding of spaces, places, locations, and how variously positioned individuals and groups live within and experience them. Qualitative geographical inquiry, however, has exposed the complexity of gaining access to and representing the situated knowledge of research participants in ways that preclude the development of rigid protocols or 'ways of doing' qualitative research. Different ways of telling, listening, and knowing require flexibility in research design and approaches. Ways of doing qualitative research need to be situated within and be sensitive to the many situations that comprise the academic geographer's field. It may be anticipated that further innovation of methods and flexible models will remain the hallmark of research concerned with the interconnections of people, place, and space.

Qualitative Research

Abstract

Qualitative research, characterized by substantially inductive and open-ended methods, is an important and accepted approach in the social sciences. Four specific features of qualitative research – understanding research participants' meanings, investigating the influence of the specific contexts in which the individuals and activities studied are situated, elucidating the processes by which these meanings and contexts lead to particular features or outcomes, and explicitly incorporating the subjectivity of the researcher – are central to qualitative research. These features shape the distinctive methods, analysis strategies, and approaches to validity and generalizability that give qualitative research its unique value for social research.

Qualitative researchers seek to understand lived experiences in context and the meanings associated with these experiences, usually from the perspective of participants. Qualitative data collection typically involves interviews, observations, and documents. Interview types include various options that range from personal, in-depth, active interviews to open-ended surveys or focus group interviews. Gubrium and Holstein (2002), in their edited volume, *Handbook of Interview Research: Context and Method*, offer a number of interview types and uses, but still critique the so-called 'interview society' that is pervasive in public life, not just in qualitative research. Likewise, observations can be exploratory, useful for documenting a setting and identifying contextual clues for future inquiry; or they can be used to compare participant perspectives with actual behavior. Finally, document collection, a secondary method in many disciplines, is of primary importance in historical studies. Documents include a variety of items: diaries, journals, photographs, census records, recordings, organizational memos, to name a few. The methods for qualitative data collection, as noted above, have a common goal of obtaining a detailed, chronological record of the events witnessed or the interviewee's statements. In actual use, these types of data overlap. For example, the use of video recording has provided an important additional way of recording interviews (individual and group), settings, and activities. Talk-aloud protocols blend interview with observation. Mobile interviewing connects the interview process to participant memories in real time. Finally, the Internet has provided many new ways of collecting data, from online interviews to accessing online discussions and social media.

What is most distinctive about qualitative research, however, is not data collection, but data analysis. In general, most qualitative data are recorded as transcripts and field notes or video, and analyzed using inductive, holistic, and narrative strategies rather than through quantification and statistical methods. Although numbers may be used in qualitative research (for example, to document how many individuals expressed a particular view or meaning, or the number of times a particular event occurred), qualitative analysis does not begin with converting the data to numerical form. There are three main types of analysis that are commonly used in qualitative research. First, in listening to and transcribing an interview, or in expanding rough field notes on an observation, researchers typically write about their reactions, interpretations, and ideas for further analysis. These writings, often called 'analytic memos' or simply 'memos,' are a form of analysis, recording the researcher's thinking about how to make sense of the data.

Second, the most prevalent form of qualitative analysis is coding, but the purpose of this is very different from quantitative coding. In the latter, the goal is to sort the data into mutually exclusive categories (typically established in advance) and counting the number of individuals, events, or responses in each category, in preparation for further statistical analysis. In qualitative research, in contrast, the main task is *developing* the analytical categories, and using them to generate themes, narratives, or even a 'grounded theory' of the phenomena. The latter was the major focus of the 'grounded theory' approach developed by Barney Glaser and Anselm Strauss – 'grounded' in the sense that the theory and the hypotheses being tested were not drawn primarily from existing theories, but were inductively generated from the data, and then tested and modified through additional data collection and analysis in a process of constant comparative analysis. More recent work in grounded theory has explored constructivist and postmodern applications of theorizing from data.

Finally, there is a less formalized and theorized form of analysis in qualitative research, one that is often implicit rather than explicit. This type of analysis, rather than fragmenting the data into categories across data sources, approaches the data more holistically, looking for connections *within* an interview, observation, or document. This is involved in many types of narrative analysis, discourse analysis, life history, and case studies, and is central to the goal of analyzing process, rather than simply providing a static description. Most qualitative studies involve all three of these forms of analysis, although the first and third may be less explicit.

The last 30 years have seen the development of a large number of computer programs (the common acronym for these is CAQDAS, for Computer-Assisted Qualitative Data Analysis Software) to facilitate the process of qualitative data analysis. Unlike statistical analysis programs, this software, although it has vastly increased in sophistication from the early forms, does not actually do the analysis; it simply facilitates the process of creating coding categories, assigning data segments to categories, and compiling all of the excerpts in a particular category for examination. The categories themselves, and the

interpretations of the categorized data, must still be created by the researcher. Although the more advanced programs can link memos to categories or data segments, and create links between categories (often called 'theory building'), their main advantage is to make the coding process easier and faster. (This can be a disadvantage if the research questions call for a primarily holistic, connecting analysis.)

A number of qualitative scholars have defined qualitative research in relation to quantitative methods. However, a precise definition of qualitative research and a clear distinction between qualitative and quantitative research remain elusive. The simplest definition, and one that is stated in some textbooks, is that qualitative research categorizes data using words (nominal- or categorical-scale measurement) and quantitative research uses numbers (ordinal- or interval-scale measurement). However, although the distinction between different scales of measurement is well established, this definition is obviously inadequate as a characterization of qualitative research, or for distinguishing qualitative from quantitative research. Qualitative researchers often use numbers in presenting their data and results, and a fixed-response survey in which the response categories are words would be seen by virtually all qualitative researchers as just as 'quantitative' as one in which the responses are numbers on a scale.

At the opposite and most complex end of the definitional scale, many qualitative researchers believe that the two approaches involve fundamentally different and irreconcilable 'paradigms,' with different philosophical assumptions about reality and how we can understand this, different goals and methods, and even different ethical premises. For example, some qualitative researchers claim that genuinely qualitative research requires a radical constructivist ontology and epistemology, one that denies the existence of any 'objective' reality; they assert that 'reality' is socially constructed by different individuals and societies, rather than existing independently of human constructions. The goal of qualitative research is seen as limited to understanding these different constructions and working to support those groups that are oppressed by the constructions of dominant groups.

This definition, which emerged from the 'paradigm wars' between qualitative and quantitative researchers during the 1970s and 1980s, also fails to stand up to scrutiny. Qualitative researchers differ widely in their philosophical assumptions; these include not only the constructivism described above, but also realism, pragmatism, postmodernism, critical approaches such as feminism and critical race theory, and many others. In addition, many qualitative researchers, particularly in applied fields, simply ignore the philosophical debates and focus on understanding their subject matter.

Because qualitative researchers usually are socialized to the method through a particular discipline, many adopt design 'types' more associated with their fields of study. Certain design types have gained popularity in specific disciplines because of the perceived alignment with foundational questions: What is the nature of reality? How does the nature of reality influence researcher access? How does this access impose a set of acceptable set of methods for exploring that reality? Some authors emphasize discrete design types that include case study, ethnograpy, phenomenology, grounded theory, and historical inquiry; the rationale is that these designs offer distinct 'recipes' for the conduct of qualitative research associated with certain approaches to inquiry. On the other hand, qualitative researchers often blend these 'recipes' to meet the needs of their specific research goals. Thus, researchers are expected to detail their decision-making process and actual methods used; in other words, qualitative researchers document the process of inquiry through an audit trail.

Given that qualitative research is not method dependent, it is tempting to argue that different forms of, and approaches to, qualitative research have what Wittgenstein called a 'family resemblance,' one that cannot be reduced to an explicit definition or distinction from quantitative research. However, there are a number of important conceptual features of qualitative approaches that are widely shared. Four of these features, mentioned above, are particularly salient for understanding qualitative research, and while not all studies will exhibit all of these, it is difficult to imagine a qualitative study that possesses none of them.

First, qualitative researchers typically focus on *meaning*, rather than simply behavior or 'attitudes.' By this term, qualitative researchers mean the beliefs, values, and perspectives held by the people studied, and as the people themselves understand these, rather than as conceptualized by the researcher. In the classic phrasing of the anthropologist Bronislaw Malinowski, a qualitative researcher seeks to understand things "from the natives' point of view," rather than by imposing prior theories or external frameworks. Doing this requires understanding what people say and do from their own perspective, and constructing what linguists and anthropologists call an 'emic' account, one grounded in the meanings that the actors themselves place on these actions and statements. This is what qualitative researchers typically mean by saying that qualitative research is interpretive – that it seeks to interpret the participants' own understandings. This does not preclude using prior theories and analytic frameworks, but it does require that the researchers not rely exclusively on these, and that they examine these theories critically, noting where they fail to capture the participants' understandings.

Second, qualitative researchers pay close attention to the *contexts* in which the individuals and events that they study occur, rather than simply attempting to generalize across contexts or individuals. Each person and situation is unique, and a qualitative study will address these differences and the effect that they have on the people and social groups studied. This is particularly true of the type of qualitative research known as case study research, in which the researcher seeks to understand a particular individual, group, or activity in its unique context, as a complex phenomenon that is intrinsically shaped by that context.

Third, qualitative researchers seek to understand *process* – not simply showing *that* the people, groups, or settings studied have certain features, but also *how* these features operate in the lives of these people and communities. As Robert Weiss described this, rather than seeking a correlation between two variables – for example, between the level of a wife's education and the presence of a companionable marriage – "[i]n qualitative studies we would look for a process through which the wife's

education or factors associated with her education express themselves in marital interaction."

Finally, qualitative researchers honor the role of *subjectivity*, sometimes defined in contrast to objectivity, across the research process. However, subjectivity is a distinct concept that acknowledges the place of personal history and experience on the part of the researcher in making decisions across the research process. These aspects of self – the researcher as instrument – encourage critical reading of qualitative findings and are recognized as a strength of certain qualitative designs. Related to this notion of subjectivity are the concepts of positionality and standpoint epistemology; these terms situate and critique qualitative inquiry through the lens of race, class, sex, gender, and other identity markers. Subjectivity is not bias; in fact, a deep awareness of one's own assumptions and focus strengthens the qualitative researcher's claim of quality. (This will be discussed in more detail in the section on validity and quality.)

These four features are shaped by a fundamental difference between quantitative and qualitative research. Quantitative researchers necessarily think about the things they study in terms of *variables* – properties of persons, settings, or events that can vary, and can thus be measured or counted, compared, and correlated. Qualitative researchers, in contrast, do not typically think in terms of variables, but in terms of entities, meanings, contexts, and processes. Their research questions, instead of focusing on correlation and comparison (*whether* there is a relationship, and its magnitude), typically address some or all of the first three of these issues – *how* and *why* things happen, how they are shaped by, and shape, their context, and what meaning these have for participants.

These features are responsible for many of the more obvious differences between qualitative and quantitative research. For example, because most of the specific, local meanings, contexts, and processes that qualitative researchers study are not well understood in advance, qualitative designs are typically inductive and flexible, allowing the researcher to modify the data collection and analysis methods during the research to better fit the particular situation and the insights that emerge from this. This flexibility is less problematic than in quantitative research, because the primary goal is not standardization for the purpose of comparison and generalization, but particular understanding.

Similarly, qualitative researchers typically study naturally existing settings, rather than contrived, experimental environments. This is because they are less interested in manipulating particular features of the environment to determine their effect on participants (i.e., treating these as variables) than in understanding these 'real-life' contexts holistically. Although some important qualitative studies have been done in experimental settings, these researchers have treated these settings *as* 'natural,' seeking to understand the meanings, actions, and processes that are found there.

Finally, a qualitative approach brings into question the goal of 'objectivity' in the sense of detachment from, and lack of influence on, the things studied. In conducting observations and interviews, a qualitative researcher is inevitably part of the situation studied, and cannot help influencing and being influenced by this, a phenomenon often termed 'reflexivity.' Rather than attempting to 'control for' this (i.e., to prevent it from being an 'extraneous variable' that may influence the relationships among other variables), qualitative researchers seek to *understand* this influence, both to prevent it from having unwanted, negative consequences, and to use it productively to investigate the phenomenon studied. This is most obvious in interviewing; the interviewer is intrinsically influencing the interviewee simply by asking questions, and the goal is not to 'standardize' the interview in order to prevent variation in the interviewer's behavior from affecting the variables studied, but to adapt to the particular interviewee and setting to best understand that person's views and perspective.

Qualitative research has a long and diverse history, arising from a variety of sources, including ethnographic research writing in anthropology since the seventeenth century (particularly that of Bronislaw Malinowski and Clifford Geertz), the work of Charles Booth, Max Weber, and the Chicago School in sociology, and the ideas of Wilhelm Wundt in psychology. Denzin and Lincoln divided the more recent history of qualitative research into seven 'moments,' emphasizing controversies and new approaches since 1950. However, most of their different 'moments' are clearly less 'stages' in the development of qualitative research than they are ongoing, diverse approaches to qualitative research; much qualitative research is still done using methods and assumptions developed before the current proliferation of approaches began.

This proliferation is perhaps the most significant feature of qualitative research at present – qualitative research includes a wide and expanding range of conceptions of what qualitative research is and can be. These include approaches that draw as much from the humanities as from the social sciences, including narrative inquiry, phenomenology, autoethnography, performance ethnography, queer theory, bricolage, and testimonio, as well as more traditional approaches such as grounded theory, case study, and participatory action research. It is beyond the scope of this article to attempt to characterize these varied strategies.

There are, however, some generalizations that can be made about qualitative methods, applying to many, but not necessarily all, approaches. First, qualitative researchers do not usually employ random or other probabilistic sampling methods, which are necessary for making statistical generalizations from a sample to the population sampled. Because their main goal is particular understanding rather than generalization, they typically use what is called 'purposeful' or 'theoretical' sampling, selecting individuals, cases, and settings that are best able to answer the researcher's questions or that are most relevant to the theory being developed. (See the later discussion of generalization in qualitative research.) In fact, many qualitative researchers avoid the use of the term 'sampling' because it connotes statistical representation of a broader population, not usually a goal of qualitative research. Instead, they use the term *selection* to remind the reader that the scope and boundaries of any qualitative study are determined by researcher choices.

The presentation of qualitative studies has traditionally been less formal and structured than in quantitative articles, more narrative in form and more open to personal details. However, this openness and diversity has increased substantially in recent work, along with the growing incorporation of humanistic and artistic forms of presentation, including performance as an alternative to written presentation of

a study's results. One such development has been the use of what has been termed 'poetic rendition'; this involves presenting the data (sometimes with some reorganization and editing) in poetic form, bringing out images and connections that might not be apparent in a prose account. Approaches such as autoethnography require researchers to include themselves as a source of data and an object of analysis. A number of analytic techniques are seeing a resurgence in recent scholarship, but incorporated through constructivist and critical theory lenses rather than the original structural perspectives, including dramaturgical analysis and portraiture. Newer forms of qualitative analysis such as meta-synthesis are gaining attention across disciplines, especially those in which pragmatic, somewhat generalizable findings are important (e.g., nursing and community health).

This proliferation of alternative types of qualitative research, and the prior polarization between qualitative and quantitative approaches that resulted from the 'paradigm wars,' led many qualitative researchers to question the traditional concepts of 'validity' and 'generalizability' as defined by quantitative researchers. Many qualitative researchers reject the concept of validity entirely, substituting terms such as 'trustworthiness' or 'authenticity' and substantially broadening the criteria used to assess these, including ethical issues such as whether their results are empowering for the people studied. Despite this, some qualitative researchers have continued to use the term 'validity,' seeking to define this in ways more appropriate for qualitative research while retaining the basic idea that validity is fundamentally about the relationship between one's theories or findings and a 'reality' to which these refer.

Generalizability has been a similarly contested concept for qualitative research. The traditional, quantitative definition (often termed 'external validity') refers to the extent to which a study's results apply to a wider range of people and settings than those actually studied. Since qualitative research typically involves much smaller samples, and rarely uses probability sampling that allows statistical generalization to the population sampled, this conception is clearly problematic for qualitative research. As a result, qualitative researchers have often employed the concept of 'transferability'; this concept does not imply that results can uncritically be generalized, but that they *may* apply more broadly, depending on differences in the nature and context of the situation to which they are transferred. This puts the burden of determining transferability on the person making the transfer, rather than on the original researcher.

Howard Becker, discussing the applicability of the results of a study of men's prisons to women's prisons, stated that such generalizations "are not about how all prisons are just the same, but about a process, the same wherever it occurs, in which variations in conditions create variations in outcomes." Robert Yin has termed this strategy 'analytic generalization' or 'generalizing to theory,' contrasting this with statistical generalization. In Becker's example, the theory involved is about the process by which a prison culture develops; this process may result in different outcomes in different contexts.

This issue of generalizability has led scholars to once again debate the value of qualitative research, thus politicizing the method in some policy venues. Still, qualitative inquiry has endured this persistent suspicion from methodological and epistemological skeptics concerned about the lack of generalizability (in the traditional quantitative sense of the term). Surviving the most strident of these debates, qualitative inquiry has proved to be an innovative genre of research for those interested in unfolding process and participant meaning, and especially in those situations where local cases do not fit the more generalized understanding.

The core issue in this methodological debate is one of quality and who gets to define it. Researchers new to qualitative inquiry may be surprised by a lack of essential standards for quality. The subjectivity of quality is particularly pertinent in qualitative inquiry where there is no pretense of universal standards for goodness, nor is there an expectation for traditional generalizability. This is not to say that qualitative inquiry is not valuable to broader audiences; rather, the issue is one of definition and conceptualization of goodness or application.

Quality does count. Every qualitative researcher, whether cognizant of it or not, applies some mental model of research goodness to his or her inquiry process. Every research choice reflects the underlying assumptions about quality in research. These mental models incorporate two aspects of research quality – technical and epistemological – that guide the reasoning process in research. Technical quality attends to methodology, specific design, and methods of data collection and analysis. Emphasizing qualitative inquiry as a creative process, Patton (2001) reminds researchers of the need for technically sound analysis, but not at the expense of the creative aspects of qualitative research.

Epistemological quality, on the other hand, introduces elements of perspective, subjectivity, and meaning inherent to qualitative inquiry. Good research is more than requiring a set of techniques to guarantee some level of validity and reliability during design and implementation. At the epistemological level, quality research questions the very representation of the study, both within and beyond the design. Why are certain participants selected? How are interview questions crafted? What observation notes are left unwritten? Who am I in this decision-making process? Epistemological quality accounts for multiple interpretations and readings of the research text; this approach assumes that many 'others' will determine the goodness of the research, including participants, journal editors and reviewers, and the reading audience.

Despite the differences between qualitative and quantitative approaches and methods, the two are not inherently incompatible; they are increasingly combined in what is typically called 'mixed method' or 'multimethod' research. (Many such studies are considered to be 'qualitatively driven'; the qualitative component of the study is primary, and its assumptions and goals largely shape the methods of the research, with the quantitative component having a supplementary role.) It is in fact the differences between the two approaches that create the complementarity that is the main strength of mixed methods research, enabling both triangulation (checking one method against another) and a deeper and wider understanding of the phenomena studied. The distinctive strengths of qualitative research – in particular, its ability to address meaning, context, and process – provide both a valuable alternative to strictly quantitative studies and complementary strategies that can be integrated with quantitative assumptions, goals, and methods.

There are numerous journals and handbooks specifically devoted to qualitative research, and qualitative studies are regularly published in many other journals. Quality of Government

Bo Rothstein, The Quality of Government Institute, University of Gothenburg, Gothenburg, Sweden

Abstract

The authors argue that the concept of quality of government should be best understood as that of having impartial government institutions. This definition avoids functionalism, ignores the contents of specific policies in favor of the procedures for how they are implemented, and pertain to the output side of the political system. They discuss this concept in relation to several proposed alternative definitions.

Introduction

The concept of quality of government – or good governance – has multiple meanings, but most generally refers to a standard or model for how states or other political entities should govern and be governed. Generally, this includes a long list of normative principles to which these entities should adhere, such as transparency, accountability, inclusiveness, effectiveness, and impartiality. Quite commonly, good governance is defined in terms of its antonyms, that is, by referring to phenomena that indicate its absence, such as corruption, nepotism, favoritism, particularism, or patrimonialism. Within policy circles of the developmental aid community, the concept has been used as an agenda for reform of developing countries, such as civil service reforms, securing property rights, or installing judicial independence. Within the academic community, the concept has been systematically linked to several highly desirable outcomes, most notably economic growth and long-term development (Rothstein, 2011).

But what, more exactly, does this new concept entail? It has been argued that there is a serious lack of conceptual precision in the use of these concepts (Fukuyama, 2011: p. 469; Andrews, 2010). In this article, the authors argue that the quality of government should be defined as having *impartial* government institutions. They will frame their justification for this conceptualization around a short intellectual background to the current issues at stake, followed by a criticism of previous efforts to define the concept. After having outlaid their own definition, the authors conclude by discussing some of the most challenging questions on the future research agenda of this field.

The Intellectual Background to the Debate

One of the major sources for the rise of the good governance and quality of government agenda has been the 'institutional turn' in the social sciences. Around 1990, three major works were published that have had a profound impact on the analysis of the importance of institutions, namely, James B. March and Johan P. Olsen's (1989) *Rediscovering Institutions*; Douglass C. North's (1990) *Institutions, Institutional Change and Economic Performance*; and Elinor Ostrom's (1990) *Governing the Commons*. Although coming from different intellectual traditions, they had one thing in common, namely, they challenged the then dominating societal views in studies of social and economic outcomes. These paradigms in the social sciences (for example, pluralism, elitism, and Marxism) all argued that variables like economic power configurations, systems of social stratifications, or the structure of class divisions were central in explaining political and thereby social and economic outcomes. Contrary to this, the institutionally orientated scholars argued that political institutions, broadly understood, were central in explaining social and economic outcomes. In political science, this became known as *Bringing the State Back In* (Evans et al., 1985; Steinmo et al., 1985).

In short, instead of focusing on how economic and sociological variables determined politics and outcomes of the political systems, the institutional approach turned the causal logic around by arguing that the character of a society's political institutions to a large extent determined its economic and social development. In common language, the institutional turn in the social sciences showed why 'the rules of the game' should have a more central role in social science research. This led to a number of interesting questions for research, such as, why societies had different institutions, what was the relation between institutions and social/economic outcomes, and if some type of institutions were better in producing valued social outcomes than others.

Different Conceptions of Quality of Government and Good Governance

To apprehend the scope of meanings attached to the concept, a series of distinctions are in order. First, good governance may be defined in terms of what it is (as a 'good in itself') or in terms of what it is good for. A prominent example of the latter approach is the definition of quality of government as what is 'good for economic development' (La Porta et al., 1999: 223). The former be called an *internal* and the latter an *external* (or functionalist) definition of good governance. In the internal case, some properties of the governance system of a country must be singled out in advance, together with a notion of why these properties make the system 'better' or of 'higher quality.' This could, for example, be the idea that good governance is to

 http://dx.doi.org/10.1016/B978-0-08-097086-8.75048-3

be equated with the rule of law. Countries abiding by this principle are then considered to have 'good governance,' regardless of whether the rule of law leads to other desirable consequences. In the external case, it is left for empirical scrutiny what properties of the system are considered to be 'good,' namely, those that are found to exert an influence on some preferable, external, outcome. In this case too, the rule of law might be considered to be part of good governance, but only to the extent that the rule of law can be shown to impact, e.g., economic growth or other desirable phenomena.

Second, good governance may be defined in terms of *procedures* or policy *content*. Procedural definitions refer to regulatory principles, codes of conduct, norms, or other value-laden criteria that constrain the forms in which politics may be conducted. Definitions demanding certain contents, by contrast, require certain policies to be enacted by the political system, such as market deregulation or state privatization.

Third, there is a fundamental difference between procedural definitions referring to the input and the output sides of the political system. The former, where *access* to public authority is regulated, is the realm of decision-making bodies, such as parliaments, cabinets, juntas, party executive committees, or royal councils. The output side concerns instead the *exercise* of public authority: how reforms are implemented, rules are enforced, court cases are decided, and so on. This is the realm of the public administration, the courts, and the law enforcement bodies of the state apparatus.

One of the most frequently used definitions of good governance has been launched by the World Bank Research Institute and reads as follows:

> The traditions and institutions by which authority in a country is exercised. This includes (1) the process by which governments are selected, monitored and replaced, (2) the capacity of the government to effectively formulate and implement sound policies, and (3) the respect of citizens and the state for the institutions that govern economic and social interactions among them.
>
> Kaufmann et al., 1999: p. 1

This definition forms the basis of the World Bank's widely used Worldwide Governance Indicators that have measures for 'voice and accountability,' 'political instability and violence,' 'government effectiveness,' 'regulatory quality,' 'rule of law,' and 'control of corruption.' This is a very broad definition and can be criticized for including both policy content ('sound policies') and procedures ('rule of law'), and for containing both the institutions for access to political power ('the process by which governments are selected') and those that exercise and implement laws and policies. In the words of Keefer (2004: p. 5), "if the study of governance extends to all questions related to how groups of people govern themselves …, then there are few subjects in all of political science and political economy that do not fall within the governance domain." Or put differently, if quality of government is everything, then maybe it is nothing.

Yet, clearly some political institutions or aspects of 'politics' must matter more than others for what should count as quality of government. The authors thus agree with the critique launched by Grindle (2007) that the World Bank's good governance agenda, not least for many poor countries, can be overwhelming and, in particular, with her argument that it fails to distinguish between various institutional particularities and more basic principles.

As an alternative, the authors propose an *internal* definition, which is purely *procedural* and based only on the *exercise* of public authority (Rothstein and Teorell, 2008). By way of defending this position, they discuss the limitations of a series of other approaches to conceptualizing quality of government.

Good Governance as the Absence of Corruption

One way out of the definitional problem would be to define quality of government and/or good governance simply as the absence of corruption. This turns out to be problematic for several reasons. First, corruption is in itself difficult to define. The standard definition is that corruption is 'the abuse of public power for private gain.' The problem with this definition is that it is relativistic since what counts as 'abuse' (or 'misuse') would vary in different parts of the world (Kurer, 2005). Needless to say, this would dramatically increase problems of operationalization and measurement but it would also carry all the difficulties connected to relativistic definitions that are known from discussions about human rights and democracy. Without a universally accepted normative standard about what forms of behavior are acceptable and appropriate, there is no way to know (and measure) what should count as 'abuse' when various systems of governance are compared in order to see if they would qualify for the epithet 'good' or not.

The second reason why quality of government cannot be equated with the absence of corruption is that there may exist many problems when governing societies are not confined to what is usually understood as corruption. A high degree of corruption is certainly an antithesis to good governance, but so are many other practices that are usually not seen as corruption, such as clientelism, lack of respect for the rule of law and property rights, nepotism, cronyism, patronage, systemic discrimination, and cases where administrative agencies are 'captured' by the interest groups that they are set out to regulate and control.

Good Governance as the Rule of Law

Perhaps as central as corruption, establishing the rule of law is usually key in any discussion on good governance and placed high on the agenda for reforming developing and transitional countries (Carothers, 1998). Still, although unequivocally embraced as a virtue of any system of good governance, the concept is rarely defined. One reason for this may of course be that the concept is inherently ambiguous and legal scholars argue over its exact meaning (Rose, 2004). To begin with, they dispute whether or not the rule of law should be given a purely procedural interpretation, bearing no implications for the actual substance of promulgated laws. Those that defend a procedural notion claim that the rule of law must be distinguished from the rule of 'good' law. Critics argue that this would allow morally detested regimes, such as Nazi Germany, to be classified as abiding by the rule of law. Against the procedural view, these critics seek to inscribe into the rule of

law various substantive moral values of liberal democracy (cf Bratton and Chang, 2006: pp. 1077–1078). Yet, even among proceduralists, who adhere to a narrower conception, ambiguities remain. Usually, more attention is paid to the internal qualities of the laws themselves – such as the need for the law to be clear, understandable, general, internally consistent, prospective, and stable – rather than to define the core principles that a political system must abide by in order to be in accordance with the rule of law.

Searching for these core principles, one may instead turn to conceptions developed within political science. Weingast (1997: p. 245) defines the rule of law as "a set of stable political rules and rights applied impartially to all citizens." Similarly, O'Donnell (2004: p. 33) states a minimal definition of the rule of law as "that whatever law exists is written down and publicly promulgated by an appropriate authority before the events meant to be regulated by it, and is fairly applied by relevant state institutions including the judiciary." He then specifies his normative term:

> By "fairly applied" I mean that the administrative application or judicial adjudication of legal rules is consistent across equivalent cases; is made without taking into consideration the class, status, or relative amounts of power held by the parties in such cases; and applies procedures that are preestablished, knowable, and allow a fair chance for the views and interests at stake in each case to be properly voiced.

The rule of law thus embodies the principle 'equality before the law.' It entails "a crucial principle of fairness – that like cases be treated alike" (O'Donnell, 2004: pp. 33–34). Although similar in spirit to the definition the authors suggest below, one problem with the rule of law approach is that good governance also applies to spheres of state action other than those directly governed by law. When public policy is to be enacted in the so-called 'human processing' areas, such as education, health care, welfare benefits, and active labor market programs, widely discretionary powers usually need to be transferred to lower level government officials and professional corps responsible for implementing policy. The reason is that they have to adapt actions to the specific circumstances in each case and it has turned out to be administratively impossible to enact precise 'rule-of-law-type' laws and regulations that can guide this. In many areas, governance is carried out by professional corps who are for the most part guided by professional standards issued by their organizations, which are not connected to 'rule of law' principles. The conclusion is that while the 'rule of law' principles in most approaches serve as a central ingredient in good government, they do not cover the full spectrum of the concept.

Good Governance and Democracy

Establishing representative democracy has often been championed as an effective antidote to everything from corruption to poverty. This is because it is linked to accountability, which helps to reduce the discretionary powers of public officials (Deininger and Mpuga, 2005: p. 171). This would indicate that democracy, quality of government, and good governance could possibly conceptually overlap, as is the case in the World Bank's definition mentioned above. This raises the question why concepts like good governance, state capacity, and quality of government are needed since we could just talk about 'democracy' as the overall standard for evaluating the polity.

The problem, however, is that empirically, there is no straightforward relationship between establishing electoral representative democracy and many features of good government. On the contrary, the relationship between measures of degree of democracy and degree of corruption shows that the curve is U-shaped or J-shaped (Montinola and Jackman, 2002; Sung, 2004; Bäck and Hadenius, 2008). Empirical research indicates that corruption is worst in countries that have newly been democratized. For example, some of the worst cases of corruption have appeared in newly democratized countries, such as Peru under its former president Fujimori (McMillan and Zoido, 2004) and Jamaica since the mid-1970s (Collier, 2006). At the more country-specific levels, one can note that studies of Italy show that politicians who stand accused of or are under investigation for corruption do not stand a lesser chance of being elected than 'clean' politicians (Chang et al., 2010). One should also keep in mind that the two states that have made the greatest progress in curbing corruption over the past few decades – Singapore and Hong Kong – have not been and still are *not* democracies (Uslaner, 2008). From this, and from the empirical research (referred to above) showing that measures of various aspects of quality of government have a much greater impact on human well-being (and perceptions of political legitimacy) than measures of democracy, it may be concluded that quality of government is different from, and should not conceptually be equated with, democracy.

Quality of Government as Government Efficiency

It would certainly be strange to argue that a government that is very inefficient or ineffective could be of high quality or produce good governance (Fukuyama, 2004). Would it then be possible to define quality of government in terms of government efficiency or effectiveness? The reasons why this is problematic are two. First, the notions of 'good' or 'high quality' usually imply other things than just economic efficiency. It is easy to think of things that a government can carry out in an efficient way that normatively would be just the opposite of 'good.' Secondly, defining concepts like quality of government in terms of administrative and regulative efficiency would border on establishing a tautology. One should bear in mind that the good governance agenda largely came about in studies trying to understand why many developing countries were unable to increase growth. Defining good governance in terms of efficiency (or efficient policies) would be tantamount to saying that efficiency causes efficiency. Not much would be gained by saying that societies with efficient (good, high-quality) governance systems produce efficiency. If not a tautology, one could say that such a definition would make the distance between independent and dependent variables minimal. Instead, what needs to be known is if societies that are socially and economically efficient, that is, are able to solve the problem of producing the amount and type of public goods they need, have institutions that are qualitatively different in their operative principles than the opposite type of societies.

In the long discussion of how representative democracy should be defined, the distinction between procedural and substantive definitions is a central theme (cf Dowding et al., 2004). Since we are striving for a universal and procedural definition that could be acceptable to groups in a democracy with, to quote John Rawls (2005: p. xvi), "a pluralism of incompatible yet reasonable," comprehensive religious, philosophical, and moral doctrines, including substantial policies in the definition is a very risky business and not likely to achieve broad-based legitimacy. This is also why the authors prefer the term 'quality of government' to the World Bank term 'good governance' since the latter has too broad connotations.

Quality of Government as Impartiality

To sum up, neither the absence of corruption, nor democracy, the rule of law, or administrative effectiveness capture what should be counted as quality of government. Moreover, including 'sound policies' in the definition raises the quite problematic question whether international (mostly economic) experts really can be expected to be in possession of reliable answers to the question of what is 'sound policies.' For example, should pensions, health care, or education be privately or publicly funded (or a mix of these)? To what extent and how should financial institutions be regulated?

Searching for a definition, it is notable that the conceptual discussion has largely been detached from normative political theories about social justice and the state. It should be obvious that when terms like 'good' or 'quality' are placed in political concepts, it is impossible to refrain from entering the normative issues that are raised in political philosophy. Obviously, a definition of quality of government need not relate to a specific set of institutional arrangements. Instead, one has to look for some *basic norm* that characterizes their institutional systems as a whole. The question is what would be the equivalent to Dahl's (1989) political equality for the 'output' side of the political system. Based on the type of rights-based liberal political theory launched by philosophers such as Brian Barry and John Rawls, the authors have suggested such a basic norm, namely, *impartiality* in the exercise of public power. This is defined in the following way: "When implementing laws and policies, government officials shall not take anything about the citizen or case into consideration that is not beforehand stipulated in the policy or the law" (Rothstein and Teorell, 2008: p. 170; cf Strömberg, 2000: p. 66). This definition is fairly precise and can be applied universally. It makes clear what basic norm is being 'abused' when corruption, clientelism, favoritism, discrimination, patronage, nepotism, or undue support to special interest groups occurs. It excludes the content of policies since it is strictly procedural.

A related suggestion on how to define quality of government launched by Mungiu-Pippidi (2006) is *universalism* (as different from *particularism*) in public policy formation and implementation. By this she means that public policies should not be directed to favoritism of individuals because they belong to particular groups of elites or have had resources to bribe officials. Yet another suggestion comes from North et al. (2009) and is *impersonal* enforcement of rules as opposed to *personalistic* forms of wielding public power. A closer inspection reveals that the differences between the notion of impartiality of these authors and the authors of this article are mostly terminological. What is important is that they all suggest a similar universal standard for what should count as quality of government and its opposite.

What does it mean to be impartial in the exercise of public power? Cupit writes: "To act impartially is to be unmoved by certain sorts of considerations – such as special relationships and personal preferences. It is to treat people alike irrespective of personal relationships and personal likes and dislikes" (Cupit, 2000; cf Barry, 1995: p. 11). The connection to 'good' or 'quality' is motivated by the fact that impartiality is the driving notion behind John Rawls' liberal right-based theory of justice. As Goodin argues: "Certainly, the antithesis of justice is favouritism" (2004: p. 100). In this context, impartiality is not a demand on actors on the input side of the political system, but first and foremost an attribute of the actions taken by civil servants, professional corpses in public service, law enforcement personnel, and the like.

Equally important, however, are the things that the norm of impartiality does *not* rule out. Since quality of government as impartiality is a procedural norm confined to the exercise of public power, one important field that is not affected by this conception is the substance of the content of policies. This builds on the idea that noncorruption implies that "a state ought to treat equally those who deserve equally" (Kurer, 2005: p. 223). This is in line with the argument that the content of public policies should not be included in the definition. Instead, it is impartiality in the exercise of power (the 'ought to treat equally' principle) that is the central component of quality of government. To treat equal does of course not imply that everyone should get the same. Only people who are in need of kidney transplantation should get one. Instead, this follows the idea of 'equal concern and respect' launched by Ronald Dworkin (1977).

It should be underlined that the argument is not that impartiality is equivalent to 'objectivity.' Still it could be said that, as a concept, objectivity has an absolute and perfectionist ring to it that implies that humans can have full knowledge of a case and weigh all things equal and come down with a decision as if the outcome was decided by some natural law process. The authors would argue that impartiality implies somewhat more human and realistic demands. First, it is about a 'matter of factness,' implying that things that according to the policy/law should not have an impact on the decision are to be left out. Secondly, it requires that the public official should not be a party to the case, neither directly nor indirectly. Moreover, the idea of quality of government as impartiality stands in sharp contrast to the public choice idea of public officials maximizing their self-interest. For example, an impartial civil servant should not be susceptible to bribery, should not decide in cases where his or her friends and relatives are involved, and should not favor any special (ethnic, economic, or any other type of organized) interest when applying laws and rules.

Conclusions

In this article, the authors have argued that impartiality provides a coherent, encompassing, and universally applicable

conception of quality of government. Elsewhere, they have also shown that it is a measurable conception (Rothstein and Teorell, 2012). This leaves two very broad sets of questions on the table. The first concerns the consequences of impartiality. After all, the new research agenda on good governance and quality of government has mostly been driven by a desire to understand what government institutions lead to preferable outcomes, such as peace, prosperity, and general human well-being. Can quality of government as impartiality live up to these expectations? In other words, can it be shown empirically that this novel theory and conception of quality of government really is what produces these outcomes?

The other central question is of course the origins of impartiality. Why have some countries in the world been more successful than others in turning their nepotistic, clientelistic, patrimonial, and corrupt government institutions into impartial state structures? Is there a common cure that could be transferred from previously successful cases to new political orders, or is each country trajectory unique, forever bound up in its own historically predetermined path dependence? One should not underestimate the problems in making transitions from low to high quality of government.

One particular problem is that, precisely because high-quality government institutions are impartial, they have no obvious interest group that is their natural supporter. The natural thing for any interest group, whether based on economic, ideological, or ethnical orientation, is to strive for political institutions and regulations that serve their particular interests and such institutions are by nature not impartial. Instead, impartial government institutions must be seen as 'public goods' type of institutions and are thereby suffering from all the well-known problems of collective action in creating goods such as various forms of 'free-riding' and others sorts of opportunistic behavior. An example of the magnitude of this problem is the Nobel Prize in Economics in 2009 that went to the political scientist Elinor Ostrom for her studies in how impartial government institutions can be established for preserving natural 'common pool' resources. While the authors think this prize was very well deserved, it should be noted that Ostrom's cases are relatively small local groups where the agents have known each other for a very long time and, as she states, have been able to develop norms about reciprocity, trust, and social capital (Ostrom, 1990: p. 35). The authors' project is to understand how such institutions can come about in much larger settings where one cannot assume the existence of such norms of reciprocity, social capital, or interpersonal trust among the agents.

Quantification in History

Abstract

The concept of quantification is defined and the evolution of quantification as a methodological tool in history is traced. Originating in the early modern period and gaining greater prominence in the nineteenth century, quantification in history came of age in the 1960s. For a time, in the 1970s and early 1980s, quantitative approaches seemed poised to revolutionize history as a field. Beginning in the mid-1980s, however, other approaches and methods, often drawn from anthropology and literature and inspired by postmodernism, began to surpass quantification in popularity, and since the late 1980s, quantitative work in history has been increasingly marginalized. But over the past decade, postmodernist approaches have lost momentum in history, and there have been some small victories by quantifiers, particularly in the field of economic history. Yet despite the fact that the approach remains indispensable for answering certain kinds of historical questions and despite the effective employment of quantitative approaches by many historically inclined scholars in other social sciences, the future of quantification in the discipline of history itself remains uncertain.

'Quantification' refers to a specific method of historical research that departs from the prevalent practice of textual analysis by actually seeking to measure changes in the past. Due to the mass of data to be handled and the complexity of the calculations involved, the application of quantitative methods usually has to be computer assisted. In contrast to a mere illustration of certain tendencies by tables or graphs, quantification tends to use analytical statistics to probe relationships between and among certain variables. Such statistical analysis also requires a high degree of formalization in the research design that formulates hypotheses to be tested and tries to combine them into models. The final aim of the quantitative approach is not just to explain a particular set of developments but to understand broader processes of change and make a theoretical contribution to some facet of historical understanding.

The Rise of Quantification

Within historical research, the development of quantitative methods was a product of a particular constellation during the 1960s. Already during the Enlightenment, some scholars had sought to describe socioeconomic developments by compiling time series, and by the middle of the nineteenth century national governments took on the task of determining population trends through a series of censuses. Nonetheless, it took the shift to the 'new social history' a century later to get historians to employ quantitative data in systematic ways and to direct historical interests away from affairs of state to mass politics, societal changes, demographic transformations, or economic growth. At the same time, the arrival of mainframe computers, followed eventually by powerful PCs, made it possible to handle large amounts of data and to use complicated statistical procedures in customized form via statistical packages such as SPSS or SAS. In order to explore these exciting new subjects with novel techniques, historians became interested in the theoretical constructs of the social sciences, borrowing eclectically from political science, sociology, or demography and somewhat less so from economics. The result of this interaction was the rapid development of a new hybrid, combining elements of historical research with social scientific analysis.

During the 1970s, this 'social science history' or 'historical social science' was successfully institutionalized. In the United States, the multitude of initiatives in history and the neighboring disciplines combined in founding the Social Science History Association in 1975, and made its annual meeting a showcase of the most innovative work. In France, many of the long-term community studies, produced by the Annales School, turned quantitative, compiling detailed time series of population, prices, or wages and probing their interrelationship. In Germany, the quantifiers linked with the theory-oriented project of a Historische Sozialwissenschaft to create a vigorous organization, called QUANTUM (Kocka, 1984). Within the decade, a spate of new journals emerged to provide publication outlets for the new work, such as the *Journal of Social History*, *Journal of Interdisciplinary History*, *Historical Methods*, *Social Science History*, *Histoire et Mésure*, and *Historical Social Research*. New textbooks (Dollar and Jensen, 1971; Floud, 1979; Jarausch and Hardy, 1991) as well as influential anthologies (Aydelotte et al., 1972; Lorwin and Price, 1972) provided a powerful platform for the propagation of quantitative research.

Research Contributions

The first field transformed by quantitatively oriented work was the new political history, which differed from its predecessor by its attention to collective phenomena (Bogue, 1983). For instance, Michael Kater investigated the rise of the Nazi movement in Germany by analyzing its membership files, indicating precisely which social stratum, religious group, gender, region, etc. joined the bandwagon at what time. For democratic societies like the United States, Lee Benson's or Alan Bogue's analysis of electoral behavior proved quite productive, since comparing returns over time made it possible to establish which polls were the critical elections when party realignments

were transformed by ethno-cultural or other factors. For parliaments without party discipline, Thomas B. Alexander's roll-call analysis also offered a powerful instrument for establishing who actually voted with whom, indicating what networks dominated legislative behavior. This retro-projection of political science methods gradually provided a firmer empirical basis for an analysis of the transformation of mass politics in the last two centuries.

The second area that was deeply affected by quantitative methods and conceptual borrowing from sociology was the new social history (Stearns, 1985). As 'history from the bottom up,' this perspective examined previously untouched serial records such as police files, employment registers, or draft books in order to infer from the behavior of ordinary people what they might have felt and thought. The appeal of this effort was the diffusion of its topics, since the labor history of the Tillys included subjects as different as proletarian living conditions and workers' collective efforts at protesting through strikes. Another question, treated, for example, by Hartmut Kaelble, concerned the pattern of social mobility, comparing the relative openness of societies to upward or downward movement over time or across borders. A related issue was the societal impact of education that required an analysis of the enrollment and composition of schools or universities in order to get at changes in educational opportunities (Ringer, 1979). These quantitative probes produced much new and sometimes conflicting information about the lower orders, the make-up of institutions, and basic trends in societal transformations.

A third area propelled by computer-assisted source collection and statistical analysis was the field of historical demography (Hareven and Vinovskis, 1978). For time periods before national censuses, the demographers faced the challenge of reaggregating vital statistics from the ground up by converting parish registers into reliable measures of natality, nuptiality, or mortality. Under the direction of Anthony Wrigley, the Cambridge population project established the outlines of a population history for England, while the demography center in Umea undertook a national project of quantifying church records so as to explain demographic changes in Sweden. American demographers like John Demos and Tamara Hareven instead combined individual life-event data to scrutinize the development of family structures from extended via stem to nuclear families and the like. Other scholars such as Roderick Floud and Richard Steckel studied changes in the height and stature of military recruits or slaves in order to develop more accurate measures of biological well-being and social deprivation. This historical demography amassed a source base for the prestatistical era and produced interesting interpretative concepts for explaining the population transition.

The final area in which quantification transformed research priorities and methods was the new economic history (Davis and Engerman, 1987). Redirecting attention away from entrepreneurship, 'cliometrics' as it was also called inspired efforts to establish indicators of national production and income for the prestatistical age as well as to transform information from manuscript censuses into published form. In the United States, a heated debate revolved around the profitability of slavery, with Robert Fogel's and Stanley Engerman's claims producing much controversy, due to their combination of economic and moral argumentation. Much attention also focused on the key factors of economic development, such as railroads, with some scholars actually arguing that their impact had been exaggerated. In Europe, discussions revolved around the pattern of industrialization instead, with some specialists like Sidney Pollard proposing a more complex regional diffusion model. On the whole, the quantitative impulse made economic history more rigorous and theoretical, but removed it at the same time further from the mainstream of historical debate.

By the 1980s, these signal contributions had managed to overcome traditionalist skepticism and to establish quantification as a new and growing subfield within the historical discipline. Though they were sometimes difficult to read for the layperson, high-quality monographs convinced reluctant granting agencies to fund major collective initiatives such as the Philadelphia Social History Project, directed by Theodore Hershberg. The number of articles with graphs and tables in respected historical journals began to reach almost one-quarter (Kousser, 1989). Opinion surveys of the profession suggested that most scholars expected quantification to be here to stay. Even if some critics still bemoaned the spottiness of graduate training in this area, the rapid rise of quantitative methods in historical research had been impressive and their future prospects seemed secure.

The Culturalist Challenge

During the decade of the 1980s, however, the seemingly unstoppable progress of the quantitative history 'project' began to stall (Johnson, 1989). By the middle of the decade, the number of quantitative journal articles and the frequency of graduate courses in quantitative techniques suddenly began to drop precipitously (Reynolds, 1998; Ruggles, 2012). This trend has continued ever since, and over the past 20 years (plus or minus five!) quantitative history has become increasingly marginalized, as a variety of other methods rose to prominence, making so-called quants seem rather quaint. Ironically, the demise of quantitative history has occurred simultaneously with the development of enhanced technology, more complete datasets, and increasingly sophisticated models and methods, which, taken together, have rendered quantitative history potentially more useful than ever before.

The factors responsible for this loss of attention are still being debated vigorously. Some scholars attribute the problems afflicting quantitative history to the initial overselling of the method by insufferable practitioners who promised more insights than their research was able to deliver. These critics, comprising largely traditionalists, have always been suspicious of the proposition that history had anything to learn from the social sciences and have long bristled at heady sentiments such as that expressed by Emmanuel Le Roy Ladurie, who predicted in 1967 that in the future "the historian will be a programmer or he will be nothing" (Rabb, 1983). The most famous (or infamous) of such critiques is almost certainly that of Carl Bridenbaugh, who in his American Historical Association presidential address in 1962 stated that "[t]he finest historians will not be those who succumb to the dehumanizing methods of the social sciences," nor those who "worship at the shrine of that Bitch-goddess, QUANTIFICATION" (Bridenbaugh, 1963). In later years, other skeptics such as Bernard Bailyn and

Lawrence Stone were more subtle, calling not for the explicit abandonment of quantification, but instead for a revival of narrative history.

Another reason was the cultural turn of many younger historians who rejected both the materialist premises and the positivist vision of most practitioners of quantitative history. To these critics, quantitative representations of the past were at once too cold, too remote, too impersonal, and too abstract. Large datasets were said to dehumanize, and 'soulless' quantifiers were assumed to be ready, like Marx's bourgeoisie, to drown all human sentiments "in the icy water of egotistical calculation" (Coclanis, 1992). Moreover, in making fetishes of rigor and precision, quantitative historians purportedly attempted to exact more from the vast, vague, largely unknowable past than historians had any right to claim. Instead, the past was reconfigured as a foreign country, to invoke the title of historian David Lowenthal's influential 1985 book (Lowenthal, 1985).

The changing demographics of the historical profession, particularly in the United States, also served to reinforce the trend toward qualitative approaches. As history opened up to women and minorities – groups, generally speaking, less inclined to pursue quantitative approaches to the past – quantitative history could be expected to decline in a relative sense. Just as women and minorities have been underrepresented in the hard sciences over the years, they have proven less interested in the more social scientific sides of history. Though both groups have embraced social history as a vehicle for their identity politics, relatively few of their members can be found in fields such as economic history, historical demography, or quantitative political history.

During the 1980s, many historians turned instead to cultural anthropology for methodological inspiration. Rejecting the rigorous, formal, and remote data-driven 'truths' sought by quantifiers, scholars interested in experience and meaning preferred in-depth microstudies, whether of single villages, small groups, or even well-documented individuals. Gradually, 'thick description' came to trump ecological regression, crude death rates, and multiple R-squares, no matter how robust! The philosophical basis of this shift to anthropology was the rise of postmodernism, which deprecated the rationalism, universalism, and empiricism of historical social science. By the late 1990s, the ascendancy of cultural studies thus left quantifiers off in a corner silently counting all by themselves.

Recent Developments

In a general sense, the spiral has continued downward for quantitative history over the past 10 years, but, when examined more closely, the overall pattern – and prognosis – for the approach becomes far more complicated. On the one hand, there is abundant evidence that quantitative approaches continue to languish among historians. With such trends as the 'history of emotions,' today few articles and books emanating from scholars in history departments employ quantitative methods; history courses in quantitative methods – and, indeed, those that once taught them – have largely been mothballed, and few departments display interest in, much less privilege, the quantitative skills of applicants to their graduate programs. Some associations and journals have withered and died – the British-based Association for History and Computing and its journal *History and Computing*, most notably – and there are virtually no job listings for quantitative historians (Anderson, 2008).

On the other hand, excellent historical work employing quantitative methods continues to appear, albeit generally by social scientists working with historical data. Economic historians, the vast majority trained as economists and working out of departments of economics, have produced an impressive body of work over the past decade, and an exceptional new journal – *Economics and Human Biology* – has become the principal venue for quantitative work in historical anthropometrics (Coclanis, 2010). Some of the interest among economic historians was spurred by the so-called Great Recession (2007–09), which led many economists to look anew at earlier periods of severe economic distress (particularly the Great Depression of the 1930s, but also the depressions of the 1870s and 1890s).

Quantitative history has flourished as well over the last decade in disciplines other than economics. Indeed, what (quantitative) historian Steven Ruggles has labeled QUASSH (quantitative social science history) is booming in allied social sciences, with top journals in demography, sociology, political science, and geography frequently featuring historical work with a quantitative bent (Ruggles, 2012). Nor does this trend begin and end with the traditional social sciences. For example, the emergence of new fields such as digital humanities and historical information science that place heavy emphasis on computing and on electronic-data storage and retrieval has proven a boon to quantitative history. Moreover, many historically minded linguists and specialists in literature have embraced quantitative methods in their work, with Stanford's Franco Moretti probably the most notable – and certainly controversial – of the literary scholars going the quantitative route (Moretti, 2005). Thus, if all is not well in history department corridors for quantitative approaches to the past, such approaches are more than holding their own in other preserves of the academic realm.

The Continued Importance of Quantification

The current disregard of quantitative methods in the discipline is unfortunate, since quantification continues to be an essential technique for historical research. Some questions can best be answered through recourse to what Sir William Petty referred to in the seventeenth century as 'Number, Weight, or Measure,' and it is more than 'physics envy' that has drawn scholars to quantitative analyses of the past. Even after conceding that many early practitioners were a bit overly zealous in their claims, it seems fair to suggest that quantitative history can provide the methodological discipline, intellectual rigor, and moral purpose that subjectivist forms of history often lack. With all due respect to such influential postmodernist thinkers such as Baudrillard and Lyotard, not every aspect of the past is positional, free-floating, and contextual. Moreover, historians are better trained to handle and preserve data from the past than social scientists who often take figures at their face value. The challenge therefore is not to abandon quantification to the

social scientists, but to create a constructive dialogue between quantitative and qualitative methods (Grossbart, 1992; Haskins and Jeffrey, 1990; Hudson, 2000).

The utility, indeed, the necessity of quantitative history seems more compelling in light of important new developments in the field. Technological constraints have eased considerably, for example, as miniaturization and digitalization in the electronics industry have advanced. Today's personal computers, programmable calculators, and other platforms offer tremendous power and, thus, computational possibilities to quantitative historians. Similarly, new developments in statistical packages, spreadsheets, GIS (geographic information systems) programs, text analysis and retrieval software, file-sharing packages, and the like have vastly expanded the array of data-gathering and analytical tools that can be used in quantitative research on historical questions.

The increasing availability of new and/or enhanced sources and datasets also presents unprecedented research opportunities. Materials readily retrievable from established institutions such as the ICPSR (Interuniversity Consortium for Political and Social Research) in Ann Arbor, Michigan, and data available online from the World Bank, the International Money Fund (IMF), the Eurostat (EU), and other governmental, quasigovernmental, and nongovernmental organizations and agencies are transforming the nature (and sites) of scholarly production. The online version of the millennial edition of the *Historical Statistics of the United States*, datasets assembled by Yale's Cambodia Genocide Program, the University of Minnesota Population Center's IPUMS (Integrated Public Use Micro Sample) Project, drawn from US census records, and the East German central cadre files – to cite but four examples – are of similar scholarly importance, and have tremendous potential as teaching tools. Various research projects undertaken under the auspices of, or promoted by the now defunct Association for History and Computing, founded in England in 1987, have proven extremely useful as well (Anderson, 2008).

At the same time, quantifiers have in recent years developed more sophisticated methods, allowing them to analyze and interpret historical questions with greater sensitivity and precision. Economic historians, for example, have used game-theoretical approaches, complex experimental approaches in laboratory settings, and advanced econometric techniques to excellent effect, and anthropometric historians have employed important new procedures from auxology and biostatistics to facilitate their reconstruction of our biological past (Komlos, 1992; Steckel, 1995; Steckel and Rose, 2002). Economic and social historians, along with historical sociologists, have also employed regression analysis in more subtle and refined ways, using temporally recursive regression procedures, when appropriate, instead of standard time-series regression techniques. And psephologists – political scientists specializing in election analysis – are using increasingly powerful analytical tools in their analyses of historical voting data.

Other quantitative historians have begun to 'push the envelope' in different ways, in so doing, often trespassing on the territory of scholars in other social sciences or even in the humanities. Thus, as procedures such as social network analysis (SNA), event-structure analysis (ESA), and quantitative language analysis are successfully employed in answering historical questions – quantitative analyses of major 'texts' in order to produce so-called semantic grammars, for example – non- and anti-quantifiers ignore the results at their peril (Anderson, 2008). In addition, quantitative historians' recent incorporation of spatial relationships into historical analysis through spatial-effects regression models and the like has produced similarly impressive results (Griffin and van der Linden, 1998).

In the second decade of the twenty-first century, the future prospects of quantification in history are therefore indistinct. Clearly, individual quantitative historians, among the profession's most avid proponents of scientific rationalism, universalism, and empiricism, are continuing to expand the frontiers of their research and are still making important contributions. But whether or not the interest of mainstream historians will return to quantification and the subfield as such will ever again recapture the excitement and energy it possessed in the 1970s remains an open question. The relative popularity of various approaches does not just depend on the quality of their scholarly work but on the larger tides of intellectual fashion. However, one unexpected development offers some cause for optimism: Though quantitative historians are hanging on for their professional lives, historically inclined political scientists, economists, demographers, and sociologists are winning kudos in their respective disciplines by bringing quantitative methods to bear on the past.

Quantification in the History of the Social Sciences

Abstract

The wide role of quantification in the modern world is not to be understood as the importation of objective methods from outside of history, but the cultivation of tools and concepts in close alliance with their contexts of use. While differentiated by field, quantitative methods have been shaped also by interactions across barriers of discipline, and even between scientific and political or administrative applications.

Quantification means, very broadly, the use of numbers to comprehend objects and events. While quantification is often identified with science, it has been equally significant for engineering, commerce, labor, government, professions, and human use of the natural environment. Quantitative methods had a crucial role in shaping the social and behavioral sciences, and remain central to them. The purpose of this article is not to supply a practical guide to quantitative tools in social science, but to examine their backgrounds and assess their broader significance from the standpoint of science studies and the history of science. In modern times, quantitative methods and the numbers they produce have assumed a powerful role in most societies as intersecting discourses of science, administration, and the public sphere. This article emphasizes the more public uses of quantification.

The broad category of quantification refers to several allied but distinct human activities. *Mathematization* means the characterization of objects and events in terms of mathematical relationships. While it is not the main topic of this article, it is of course relevant. The expression of scientific theories in mathematical terms has provided one important basis for relying on quantitative or numerical data. There have been other reasons of a technical, administrative, or moral kind. Among the more empirical forms of quantification, *measurement* grew out of such practical activities as surveying lands or buying and selling. *Counting*, the basic tool for assigning numbers to sets of discrete objects, was deployed for such tasks as inventorying one's possessions or tallying populations. *Calculation* refers loosely to methods for combining and manipulating numerical information into more readily useable forms. *Statistics*, a wide-ranging body of methods for analyzing quantitative information, is discussed historically in other articles in these volumes, and receives also some attention here.

Theories and Measures

As early as the 1660s, and more systematically from about 1830, social and economic investigators in the European world held up quantification as the proper method of science. The growth of university-based social disciplines from about 1880, and especially after 1930, was attended by a widespread faith that through numbers, social research could be made genuinely scientific. A generation or more of positivistically inclined researchers looked to systematic measurement as the proper foundation for solid, mathematized theory. Some compared its progress with the development of physics in the seventeenth century, and anticipated a breakthrough in the near future.

The most influential historical and philosophical writers on science in the postwar period took almost the opposite view. Alexandre Koyré (1968), whose philosophical studies of seventeenth-century science inspired the first generation of professional historians of science in the Anglophone world, challenged the supposition that indiscriminate data collection would ever lead to serious science. He doubted, for example, that Galileo had learned much about the laws of motion from rolling balls down inclined planes. The new kinematics applied not to real objects, he argued, but to abstract bodies in geometrical space. Galileo derived his law of falling bodies mainly by working out the logical consequences of what he already knew. This mathematical and metaphysical work was, for Koyré, the most important achievement of the new science. Indeed, only through theory had the measures attained scientific meaning. Thomas Kuhn (1961, 1976) reaffirmed Koyré's broad argument and provided a historical perspective that reached forward to the nineteenth century. The most successful sciences of the seventeenth-century 'Scientific Revolution,' including mechanics, astronomy, and geometrical optics, had already been mathematical in ancient times. The more Baconian experimental studies of the early modern period were comparatively ineffective until a 'Second Scientific Revolution,' beginning around 1800, when new scientific objects such as electricity and heat began to be comprehended mathematically.

Scholars in science studies since about 1980 have inclined to dethrone theory in favor of a more respectful attention to the practices and material culture of science. Accordingly, they take more seriously the quantification of phenomena that had not been grasped by exact laws. Just as the life of experiment has never been strictly subordinated to theory, so numbers have often functioned independently of higher mathematics. They are linked not just to theoretical science, but also, and perhaps even more consequentially, to economic and administrative changes. The history of ideas alone cannot grasp their full significance.

Quantities and Standards

Quantity is not first of all the language of science, imported as something alien into everyday affairs, but an indispensable part

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03227-X

of the fabric of life. Yet the aspiration to science has gone a long way toward reshaping the role of numbers and measures in the world. In this – as Max Weber suggested – we find much in common between bureaucratic and scientific rationality. Mathematics has often, and plausibly, been held up as an exemplar of universalized knowledge. The rules of arithmetic, or constants like π, are the same everywhere, at least in principle. Yet the universalism of measures and numbers, particularly when these have empirical content, has been achieved only within confined human spaces, and only by overcoming great obstacles. Even now, even in the industrialized West, quantities and prices are managed in everyday activities such as shopping by techniques quite different from those taught in schools (Lave, 1986). Before the rise of modern science, in the preindustrial world, quantification had very different meanings. Numbers were pervasive, but for most purposes their use and meanings were thoroughly local. The process through which they gained general validity is one of the crucial transformations of modern life.

A Plethora of Units

As Witold Kula (1986) has shown, measures remained immensely variable in Europe as late as the eighteenth century. This was partly by design, since small cities and lesser states often claimed the right to define their own weights and measures as a mark of autonomy and an obstacle to rule by central authorities. A diversity of measures, however, is the natural state of things wherever the pressures of commerce and administration have been insufficient to bring about unification. At a local level, authorities took some pains to reduce the ambiguity of measurement. A bushel measure, valid for the region, would often be fixed to the town hall, and could be used to settle disputes. In the next town, however, its volume would be slightly different, and over greater distances they varied considerably. The subtle geography of measures, moreover, was not defined exclusively by distance. Milk, oil, and wine came in different units; measures of cloth depended on the width of looms, and hence on the costliness of fabric and weave. The practices of measurement, too, were complexly nuanced. A bushel measure, even if the volume was fixed, could be tall and narrow or short and wide; the wheat might or might not be compacted by being poured in from a considerable height; and a complex set of conditions governed whether to heap the bushel, and by how much. Parties to a transaction often negotiated about measures rather than about prices. Add to this the consideration that almost nothing was decimalized, not even money, and it is evident that arithmetical calculation provided no fixed routine for managing affairs or settling disputes (Kula, 1986; Frängsmyr et al., 1990). The conversions required by trade provided an important source of employment for mathematicians.

The simplification and standardization of measures was encouraged by the expansion of long-distance trade, but was achieved primarily by governments in alliance with scientists. Among Europeans, it was the British who came nearest to creating uniformity of measures in the eighteenth century. A more systematic, almost Utopian, scheme, the metric system, was initiated in the 1790s under the French Revolution. In its most ambitious form this included a new calendar using months of 30 days divided into weeks of 10 days, and even a few decimalized clocks, beating out a hundred seconds per minute. The meter was set so that 10 million of them would reach from pole to equator, in the vain hope of integrating geodetic and astronomical measures with those on a human scale (Gillispie, 2004). To this end, bold expeditions were sent out into a disordered countryside to survey and measure a meridian. Although the meter was justified in part as a response to organized petitions (*cahiers de doléance*) calling for fixed measures as protection against seigniorial discretion, the highly rationalized metric system of decimalized conversions and strange Greek names – of milliliters, kilometers, and centigrams – went well beyond this. Not until the July Monarchy, after 1830, did the metric system begin to succeed even in France (Alder, 1995, 2002). In time, however, it has come to provide a common set of measures for most of the world, with the United States a notable, though partial, holdout.

A precise and maximally rigorous definition of units is a basic element in the infrastructure of modern life. The role of standardized measures in systems of manufacturing based on interchangeable parts is widely recognized. They are indispensable also for large-scale networks such as electric power distribution, telephony, and, by now, computers and the Internet. A collaboration of scientists and bureaucrats was required to create them. In some cases, as with the electrical units defined in the later nineteenth century, eminent scientists such as James Clerk Maxwell, William Thomson (Lord Kelvin), and Hermann von Helmholtz were deeply involved in the definition of standards.

Other units, far from the domain of scientific theory, play an indispensable role in the regulation of modern life. Environmental agencies, for example, deploy measures of effluent concentrations, to regulate pollutants. They depend on meticulous specification not only of instruments, but also of sampling methods, training of technicians, custody of materials, and so on. Since penalties and taxes often depend on them, they are always vulnerable to challenge. In this domain, as in many others, an immense apparatus of instrumentation and control lies behind what scientists and citizens have the luxury (usually) of regarding as 'raw,' or merely 'descriptive,' data.

Producing Uniformity

Units and instruments are not by themselves sufficient to quantify effectively. A quantifiable world contains reasonably homogeneous objects, objects whose measures can be compared, or that can be grouped together and counted. Nature and unregulated human labor produce a few of these, though real uniformity occurs mainly on a scale – for example, the molecular one – that is not readily accessible to the human senses. Physics was quantified partly in terms of abstractly 'mathematical' entities, such as forces, and partly through increasingly rigorous experimental controls, involving an expanding apparatus of instruments.

In the social world, where quantification is also a tool of administration, these same regulatory processes have helped to produce new quantifiable entities. The investigation and

compensation of joblessness, for example, solidified the category of 'the unemployed.' In most countries, the official definition of an unemployed person has been linked to a state obligation to provide benefits. To collect unemployment insurance requires that a person meet certain standards, which are more or less closely monitored, and to which persons who lack work are encouraged to conform. They also must enroll themselves, thereby adding their unit datum to the numbers. The point here is not that government offices cause people to be without work, though mechanisms of compensation will certainly affect the rates. It is that official categories sharpen definitions, and so help to create countable entities. Those entities are also vulnerable to manipulation: a looser definition will be popular among those collecting benefits while a tighter one will not only reduce costs, but in the same stroke will lower the official unemployment measure. Most human and social types are variable, or at least fuzzy at the margins (Hacking, 1995). Measurement, for example, of crime, ethnicity, or mental illness, is allied to processes that make them more uniform, and hence countable. Economic categories such as profits, investment, and trade are dependent on the processes through which they are recorded and regulated. Financial and other measures can be *performative* in the sense that a theoretical articulation may cause values in the world to conform more closely to them (MacKenzie, 2006). But there is another side to this dialectic, since the thinness of quantitative description can invite manipulation, leading sometimes to breakdown and even catastrophic failure of an order based on measurement.

The Authority of Calculation

Numbers and measures are not merely tools of description and analysis. They work also as guides to action, especially public action. An explicit and formal analysis, often largely quantitative in form, is by now required for a variety of public decisions involving investment or regulation. Business organizations depend increasingly on measures and projections in order to make decisions. These analyses are often expressed in money terms, and their modern expansion attests to the triumph of capitalism. But public reliance on economic quantification is by no means a mere imitation of its commercial uses. The tools of quantitative analysis were developed as much for government as for business purposes, and have become increasingly dependent on academic researchers. In the background is an evolving political and administrative culture, reflecting changes in the status and composition of elites.

Commensuration

It is characteristically modern to suppose that a conscientious decision should involve explicit consideration of the available data. Decision by calculation goes beyond this, requiring a course of action to be dictated 'objectively' by facts. One prototype of this ideal of public reason is benefit–cost analysis (BCA). In practice, BCA involves predictions in many domains, including weather patterns, health, hydrology, ecology, and commerce, but its most distinctive aspect is the attempt to convert a great diversity of considerations into a common financial metric. The obstacles to commensuration are most compelling in regard to such considerations as human lives lost or saved, the disappearance of biological populations, or the degradation of a beautiful landscape. In public debate, such exchanges may seem profoundly immoral. Yet commensuration flourishes particularly as a strategy of simplifying, and perhaps of ranking, for lay people trying to make choices regarding complex problems for which they lack real access to specialized tools of knowledge (Espeland and Stevens, 1998).

Economics provides a rationale for much commensuration, but BCA did not develop out of theoretical economics. It was imposed by the U.S. Congress and by the exigencies of legal and administrative challenges during a massive expansion of federal water projects beginning in the 1930s. Engineers, not economists, initially faced the immense difficulties of incorporating life, health, recreation, and scenic beauty along with economic development as they proffered measures of the costs and benefits of water projects. Despite political opposition to some of these measures, a political logic of rationalized choice made them necessary nonetheless. The task was to devise methods that would hold up to administrative and legal challenge. In this context, what was not quantified tended to disappear, and the experts found it necessary to put aside what seemed the implausibility or even immorality of expressing everything, including lives saved or lost and traditional ties to the land, as a sum of money. Beginning in the 1950s, economists and social scientists were recruited into agencies like the U.S. Army Corps of Engineers and the Bureau of Reclamation to provide more consistent or more acceptable solutions to these thorny problems. Finally, during the 1960s, BCA emerged as an applied field within welfare economics (Porter, 1995; Espeland, 1998).

Trust and Impersonality

Academic problems of social measurement and commensuration are thus embedded in social and political conditions that put a premium on scientific objectivity in the specific sense of freedom from personal or self-interested bias. Since David Hume, at least, facts have often been sharply distinguished from values, and for some purposes the credibility of science is enhanced by its separation from their 'subjective' domain. The ambition to provide a scientific, possibly quantitative, basis for public decisions remained quixotic or utopian so long as an aristocratic political class retained power. Few would assent now to Frédéric Le Play's assessment that numbers became necessary as a second-best option under democratic governments, in the wake of revolution, when leaders no longer possessed the inherited wisdom of birth and experience (Porter, 2011). Yet the aspiration to replace judgment with objective, quantitative rules grew up in situations where elite authority had become suspect.

The move by American state engineers to an increasingly rigorous benefit-cost methodology was a response to systematic challenge, and exemplifies this point. So also do other exemplary tools of 'mechanical objectivity.' Social and medical researchers have been criticized for preferring the impersonal rigor of the statistically significant result over proper measures of quantities that matter for health and

wealth (Ziliak and McCloskey, 2008). Accountants did not willingly abandon what many saw as their professional responsibility to offer an expert assessment of the financial condition of firms. These choices may be understood as a sacrifice of meaning for the sake of quantified objectivity, whose ascent is part of a broad cultural and political history of the twentieth century. Some basic features of that history would include the growth of government, bureaucratic conflict, resistance to administrative secrecy, and public distrust of 'bureaucracy.' The unprecedented quantitative enthusiasm of postwar social science involved, along with its optimism about the 'methods' of science, an ethic of renunciation that more and more was to be anchored in rules of method rather than high moral character (Porter, 2004).

A Historical Perspective on Social Science Quantification

Reflective accounts about the social and behavioral sciences have often supposed that these fields have short histories, and that the pursuit of quantification means following the path of natural science triumphant. But the rise of a quantitative ethos in natural science can be dated no earlier than the early eighteenth century. Systematic measurement until then was almost confined to astronomy, and with it astrology, which extended over every inhabited continent. For a long time, astronomical measurement was geometrical and not numerical. Its purposes were practical as well as scientific: to survey land, navigate ships, calculate calendars, and horoscopes. Barometers and thermometers helped to extend the domain of measurement into meteorology during the seventeenth century. Measurement in early modern Europe was associated as closely with natural history as with experimental physics. By 1750, savants bearing instruments wandered the Earth measuring mountains and other natural wonders, conjoining precision to their appreciation of nature. The development of an exact science of electricity in the later eighteenth century marked the advent of systematic experimental quantification (Heilbron, 1979). Measurement had also become routine in technological endeavors, such as mineral assaying, decades before Lavoisier and his contemporaries began to insist on its centrality to chemistry.

From this perspective, it would be difficult to argue that political and economic studies lagged behind natural science in their reliance on numbers. Among the early members of the Royal Society of London, founded in 1660, were William Petty and John Graunt. Petty announced a new science of 'political arithmetic,' which in his hands involved speculative estimates of population and of wealth. Graunt is noted for his more strictly empirical compilations from the London bills of mortality. Just a few decades later, Jan de Wit, the Dutch Stadtholder (magistrate), used rudimentary probability theory to assign rates for the sale of annuities, and the astronomer Edmond Halley calculated the first mortality table. Political arithmetic, which entailed the compilation as well as the analysis of demographic and medical records, flourished in the eighteenth century, and public health was among the earliest and most influential of the quantitative studies. At the same time, probability theory was pursued as a mathematical theory of belief and credibility (Hacking, 1975; Daston, 1988; Rusnock, 2002). The *philosophe* and mathematician Condorcet, a leader of the French Revolution who then was hunted down by it, hoped to develop probability into the theoretical basis for elections and judicial decisions (Baker, 1975).

The Nineteenth Century and the Rise of Statistics

By the early nineteenth century, as Kuhn observed, the natural historical investigation of heat, electricity, and the physics of light had given way to sciences that were both mathematical and quantitative. Possibly the analysis of mortality records for insurance can be regarded as comparable in certain respects. But the explosive growth of quantification beginning in the 1820s, what Ian Hacking (1990) has called an 'avalanche of printed numbers,' was not concentrated in the experimental sciences. Rather, it involved systematic surveys of stellar positions, terrestrial magnetism, weather phenomena, tides, plant and animal distributions, and social statistics.

The collection and investigation of social numbers had expanded gradually over the course of the eighteenth century. Few eighteenth-century states had the bureaucratic means to conduct a full census, and most were disinclined to release such sensitive information to their enemies or even to their subjects. In many places, too, the people would have viewed census officials as harbingers of new taxes or military conscription, and in Britain the census was blocked by a gentry class that refused to be counted. In contrast to piecemeal efforts at home, there were some systematic surveys abroad, the machinery of centralized state information gathering having been turned loose first of all in colonial situations. Among European states, Sweden pioneered the regular census, in 1749; its results remained secret until 1764. The French used sampling, of a sort, and enlisted mathematicians such as Pierre Simon Laplace to estimate the population. The U.S. census of 1790 heralded a new era of regular, public censuses, which were encouraged in Europe by French military conquest and by the pressure of wartime mobilization. The British instituted their decennial census in 1801. Finally in the 1830s, bureaucratic professionals began to take over the collection of social and economic numbers in the most advanced European states.

At the same time, an increasing pace of quantitative study by voluntary organizations made 'statistics' a plausible 'science of society.' One model for it was developed by the Belgian Adolphe Quetelet, whose quantitative pursuits ranged from observational astronomy and meteorology to the bureaucratic organization of census work. He argued for an alliance of data gathering with mathematical probability, in the quest to uncover 'social laws.' Apart from life insurance, however, most statistical collection was under the control of reformers and administrators with little mathematical knowledge. Their enthusiasm for counting was perhaps indiscriminate, yet it was nurtured by specific anxieties about poverty, sanitation, epidemic disease, economic dislocation, and urban unrest. Social investigation, still more than natural science, was an object of contest, and there were active efforts to organize a social science to speak for working people (Yeo, 1996). Karl Marx's immense statistical labors for his *Capital*, drawing mainly from official British inquiries whose

results he praised as honest and reliable, testify impressively to the credibility of public numbers. Middle-class organizations had more staying power than working-class ones, and better standing to claim the mantle of 'social science.' In Britain, the Statistical Society of London (founded 1834) joined bureaucrats with professionals and even aristocratic political leaders. In Germany, statistics became a university field, which, from about 1860 to 1900, combined empirical quantification with a historicized 'national economics,' in a quest for state action on behalf of workers and peasants. Some of the founders of social science in America were brought up in this tradition, as was Max Weber. Emile Durkheim, too, engaged with it, as his *Suicide* of 1897 plainly attests (Porter, 1986).

The nineteenth-century science of statistics embraced much of the subject matter of the modern social sciences. It overlapped, and sometimes competed, with political economy, political science, geography, anthropology, ethnology, sociology, and demography. These stood for genres, more or less distinct, though not for anything so definite as modern professional disciplines. Their quantitative methods were not identical, but neither were they sharply differentiated from each other or from measurement in biology. There was much uncertainty and debate from 1830 through the end of the century as to whether statistics was a science, with its own subject matter, or only a method. It was resolutely empirical, to the point that some considered sampling too speculative. Far from being allied to any mathematical social science, statistics was more often at war with deduction and abstract theory. Some, like the economist William Stanley Jevons, would claim that political economy should be mathematical because it was inherently quantitative, but he could not attach the mathematical formulations he introduced to empirical numbers.

Quantification in the Modern Social and Behavioral Sciences

Toward the end of the nineteenth century, a more mathematical field of statistics began to develop. The most influential form of the new statistics was British biometric version created by Francis Galton and Karl Pearson (Stigler, 1986). At almost the same time, however, distinct social and behavioral sciences began to crystallize, in part around somewhat distinct quantitative methods. All were conceived as ways to enhance the scientific standing of their fields, and each was engaged also with issues of politics, policy, and the management of economies and populations. The typology to follow is intended to be suggestive, and certainly cannot be exhaustive.

Physical Anthropology and Eugenics

The measurement of humans was carried out for bureaucratic as well as scientific purposes throughout the nineteenth century. The increasing concern with race in anthropology was linked to a preoccupation with skulls, whose measures were used to distinguish distinct 'races' of Europeans. What Francis Galton called 'correlation' was developed to measure the interconnections among physical human characteristics, their perpetuation from one generation to another, and their relation to measures of merit or achievement.

Education and Psychology

Correlation provided also a solution to a problem of contemporary psychophysics, related to education. Gustav Theodor Fechner began applying the methods of error theory to the measurement of sensory discrimination in the mid-nineteenth century. Systematic use of experimental randomization was developed for studies of this kind (Dehue, 1997). They provided also a wide field of application for correlational methods. Did childhood study of dead languages really train the mind for speedier or more thorough learning of other subjects, such as science, history, or literature? The growth of mental testing in the early twentieth century posed a more general question of correlations. To what extent did students who proved themselves adept in some particular study excel also in others? Charles Spearman's *g*, or general intelligence, and the 'intelligence quotient' or IQ, presupposed a basic unity of the mental faculties. Psychometricians and educational psychologists developed a body of statistical methods to measure this intelligence, or to decompose it, and to assess the relations of its components. The measurement of intelligence assumed an important role in sorting institutionalized populations of students, soldiers, and the like (Zenderland, 1998; Carson, 2007).

From the 1930s, as psychology turned resolutely experimental, quantification became mandatory. Once again, educational psychology as well as parapsychology took the lead in the assimilation of novel methods of experimental design and analysis. The new paradigm of a proper experiment involved a randomized design of control and experimental populations, yielding results that would, in most cases, be subjected to analysis of variance. A worthwhile result was defined in part by a test of significance: the 'null hypothesis' that the treatment had no effect should be rejected at some specified level, commonly 0.05. This was the methodology of the English statistician R. A. Fisher, and for half a century or more beginning in the 1920s his name was practically synonymous with modern statistics (Gigerenzer et al., 1989).

Econometrics and Economics

Economic numbers were preeminent among the concerns of statistics from the eighteenth century. From the late nineteenth century, new tools grew up with new quantified objects such as unemployment and the cost of living (Stapleford, 2009). A new economic mathematics of marginal utility appeared in the 1870s and was self-consciously reconciled to the classical tradition in the 1890s by Alfred Marshall. His work included abundant graphical illustrations, but these presented curves that could not readily be measured. The sources of econometrics are largely distinct. From origins in the 1870s to the establishment of a society and a journal in the 1930s, the field focused on the study of business cycles (Morgan, 1990). Econometricians took their numbers where they could get them, often from public sources. They were highly dependent on national accounts, prepared by governments, and indeed participated in structuring these accounts. The paradigmatic statistical tool of econometrics, adapted from biometrics mainly after 1950, was regression analysis.

Surveys

From the founding of statistical societies in the 1830s, social science has relied on surveys to understand social problems and learn about how the lives and opinions of ordinary people. Charles Booth's monumental studies of East London beginning in the 1880s inspired a movement of surveys of towns and regions in Britain and America. For most of the nineteenth century, statisticians typically aimed to count exhaustively, but then began relying more and more on 'representative' sampling, which was valued for its speed and adaptability. The origins of survey sampling are partly conceptual, but were tied to specific practical problems, as in late imperial Russian efforts by officials, sometimes allied to mathematicians, to manage budgets for communities of recently freed serfs. Arthur Bowley and then Jerzy Neyman worked to develop rigorous sampling methods that would permit generalization using probability theory. The techniques of survey sampling have linked sociology and political science to marketing and political campaigns (Desrosières, 1998; Mespoulet, 2001; Igo, 2007).

Medicine

The statistics of public health, including the treatment of mental illness, was long focused mainly on gathering information and presenting it in tables. Pearson's biometric statistics began the formalization of experimental and quasi-experimental methods, which were reshaped according to a new theoretical logic by Fisher. Health officials institutionalized the randomized, controlled trial in medicine from the 1940s. It soon came to define the 'gold standard' in experimental medicine. More broadly, statistical data and analyses, including 'metastatistical' methods for combining the results of different studies, have become exemplary not just of 'evidence-based medicine,' but of evidence itself in its most public, bureaucratically acceptable form (Marks, 1997; Jorland et al., 2005).

Conclusion

Quantification is as central to social as to natural science. In an era of vast interlinked computational systems and almost infinite data banks, its public prominence and its secret manipulations are more impressive than ever. The expansion of quantification over the last three centuries reveals some key characteristics of the social and behavioral disciplines, among them, the drive for the status of science, the role of applied studies in forming academic ones, the shaping of knowledge by data technologies, and the often problematic relationship of theoretical to empirical work. The quantification of human science draws from centuries of history, and is by no means a mere product of the modern effort to attain scientific standing. Indeed, the advance of measurement and statistical analysis in social science is not distinctively academic, but has been stimulated by administrative and political demands. Yet quantification in social science has, for two centuries, been enveloped in a certain mystique, regarded as an indication of rigor or at least of scientific maturity. We should understand it not as the key to all mysteries, but as a powerful set of tools and concepts, to be integrated as much as possible with theoretical understanding and with other ways of comprehending social phenomena.

Quantifiers

Abstract

Quantifiers are freestanding expressions whose meanings involve the notion of quantity. The basic semantic structure of quantification is bipartite, consisting of the quantifier itself plus the expression that it quantifies. Quantification has traditionally been of great interest to semanticists, logicians, and philosophers of language, due at least in part to the perceived 'logical' or 'mathematical' nature of the meanings involved. However, in different languages, such meanings are often expressed by means of very different morphosyntactic strategies. Quantifiers may be classified in terms of their inherent meanings, as count or mass; as existential, midrange, or universal; as strong or weak; and as increasing, decreasing, or neither. They may also be classified in terms of their role within the sentence, as nominal or verbal, as continuous or discontinuous, and as simple or scopal. In general, quantifiers do not constitute a coherent grammatical category, either within individual languages or crosslinguistically. Although prototypical instances of quantifiers are easily identifiable, there are many cases in which a given expression straddles the boundary of what counts as a quantifier, either because it is not clearly freestanding or because its meaning shades off into other domains not generally characterized as quantificational.

Introduction

Quantifiers are freestanding expressions whose meanings involve the notion of quantity, such as, in English, *three*, *several*, *numerous*, *most*, *every*, *one hundred and twenty three*, *all but seventeen*, and so forth.

The basic semantic structure of quantification is bipartite, consisting of the quantifier itself plus the expression that it quantifies. For example, in a sentence such as *John saw three cats*, *three* is the quantifier, and *cats* the quantified expression.

Quantification has traditionally been of great interest to semanticists, logicians, and philosophers of language, due at least in part to the perceived 'logical' or 'mathematical' nature of the meanings involved. As such, it is striking to observe how such basic and seemingly immutable meanings may, in different languages, be expressed with very different morphosyntactic strategies, exhibiting a great degree of crosslinguistic variation. Some seminal recent studies of quantification include Keenan and Westerståhl (2011), Westerståhl (2011), and Keenan and Paperno (2012).

Quantifiers may be classified internally, with respect to their morphosyntactic structure and basic semantic properties. In addition, they may be classified externally, with regard to the syntactic and semantic relationships between the quantifiers and the quantified expressions and/or the remainder of the sentences in which they occur.

Internal Classifications

Internal classifications of quantification make reference to a variety of fundamental morphosyntactic and semantic properties.

Mass and Count Quantifiers

One of the most basic distinctions is between mass and count quantifiers (Pelletier, 1979; Allan, 1980). Mass quantifiers constitute expressions which denote an undifferentiated homogeneous mass; for example, English *much* is a mass quantifier because it forms expressions such as much milk, much cake. In contrast, count quantifiers constitute expressions which refer to one or more countable units of characteristic size and shape; for example, English *many* is a count quantifier because it forms expressions such as *many cats*, *many cakes*. Whereas many quantifiers belong to just one of the two types, mass or count, some quantifiers are undifferentiated with respect to the mass/count distinction and may appear in expressions of either kind.

An interesting case is that of the so-called 'classifier languages,' many of which are located in the East Asian linguistic region (Craig, 1986; see example (4) below). In such languages, many or all of the count quantifiers cannot occur in immediate construction with the noun that they quantify; instead, the quantifier must occur in construction with a classifier, and the quantifier-plus-classifier constituent may then occur in construction with the noun. Typically, the classifier makes reference to various characteristics – size, shape, function, and so forth – of the quantified noun. Accordingly, different nouns often require different classifiers. However, in some cases, different classifiers may occur with the same noun, sometimes resulting in subtle differences in meaning (*see* Classifiers, Linguistics of).

Existential and Universal Quantifiers

Of particular interest to logicians are the existential and universal quantifiers (Vendler, 1967; Heim, 1982; Gil, 1995). Existential quantifiers, such as English *some* and *a*(*n*), form expressions denoting at least a minimal, nonzero amount or number of the quantified expression, for example, *some water*, *a boy*. Universal quantifiers, such as English *all* and *every*, form expressions referring to an exhaustive amount or number of the quantified expression, for example, *all the water*, *every boy*. Existential and universal quantifiers are semantically related to each other through negation by means of the classical 'square of opposition': thus, in English, *Not a boy came* is equivalent

to *All the boys did not come*, and *Not all the boys came* is equivalent to *A boy did not come*.

Existential quantification, in many languages, is inextricably intertwined with singular number and/or indefiniteness: in some cases they are expressed identically, while in other cases they are expressed by means of the same marker occurring in different constructions, or by means of similar though not identical markers. Universal quantification, too, is expressed in a variety of different ways across languages. Some languages, such as English, do have 'dedicated' universal quantifiers, that is to say, words such as *all* and *every*, whose primary or exclusive function is the expression of universal quantification. However, many other languages lack such words, instead making use of more complex circumlocutions if and when the expressive need arises.

Given the importance of existential and universal quantifiers in mathematical logic, it is worthy of note how relatively unimportant these quantifiers are within the grammatical systems of languages. It is indeed not all that common to find a single form, in any language, whose interpretation corresponds precisely and unproblematically to either the existential or the universal quantifier. Moreover, there is probably no language in which expressions of existential and universal quantification constitute a natural grammatical class to the exclusion of other expressions. The diversity of morphosyntactic expression of existential and universal quantifiers across the world's languages suggests that, although greatly valued by logicians, they may not be endowed with privileged status vis-à-vis the structure of language.

Midrange Quantifiers

'In between' the existential and the universal quantifiers lie a variety of midrange quantifiers, such as, in English, *few*, *several*, *many*, *most*, and so forth. Among the midrange quantifiers, a particularly privileged category is that of cardinal numerals – quantifiers which refer to natural numbers, for example, *one*, *two*, *thirteen*, *one hundred and twenty seven* (Menninger, 1969; Hurford, 1975). Complex phrasal numerals often make use of syntactic patterns available elsewhere in the language; however, in addition, they sometimes exhibit unique structural features not found in other grammatical domains. For example, in Georgian, phrasal numerals are exceptional in that they are the only multiword expressions that may undergo reduplication (thereby forming distributive-share numerals of the kind discussed in the Section Scope and Scopal Quantifiers below).

Other Internal Classifications

Quantifiers are sometimes classified as either *strong* (alternatively referred to as definite) or *weak* (indefinite) (Milsark, 1977). Strong quantifiers, such as English *all* and *most*, are inherently definite in their meaning, whereas weak quantifiers, such as English *some* and *three*, are not. Strong and weak quantifiers often exhibit different syntactic behavior; for example, strong quantifiers are typically awkward or ungrammatical in existential sentences, e.g., *There is all the water on the floor*.

Some further semantic distinctions are captured by the categories of *increasing* (alternatively referred to as upward entailing) and *decreasing* (or downward entailing) (Keenan and Stavi, 1986). A quantifier is increasing if a sentence containing it would be logically true in a situation in which the amount or number of quantified expressions involved is larger than that explicitly stipulated by the quantifier, for example, *at least three*. Conversely, a quantifier is decreasing if a sentence containing it would be logically true in a situation in which the amount or number of quantified expressions involved is smaller than that explicitly stipulated by the quantifier, for example, *at most three*. Other quantifiers are neither increasing nor decreasing, for example, *exactly three*.

An interesting problem is posed by simple monomorphemic quantifiers such as *three*. At first blush, such quantifiers appear to be neither increasing nor decreasing: if somebody says *There are three cats on the bed*, the mental picture that is conjured up is, of course, one of three cats, not two, or four, or any other number. However, a moment's reflection will reveal an important asymmetry. If in fact there are exactly two cats on the bed, then the above sentence is clearly false. In contrast, if there are exactly four cats on the bed, then, in most contexts, the above sentence would obviously be misleading and inappropriate – but it would not, strictly speaking, be false. Thus, while the pragmatic appropriateness conditions of *three* resemble those of *exactly three*, the actual truth conditions of *three* are identical to those of *at least three*. Hence, *three* is, in fact, increasing.

External Classifications

External classifications of quantification make reference to the morphosyntactic and semantic relationships which obtain between the quantifiers and the quantified expressions and/or the remainder of the sentences in which they occur.

Nominal and Verbal Quantifiers

One basic semantic classification relates to the category of the quantified expression, specifically whether it is of a nominal or verbal nature (Gil, 1993). For example, in the English sentence *John saw three cats*, the numeral *three* quantifies a noun; accordingly this sentence illustrates nominal quantification. In contrast, in the sentence *John sang three times*, the numeral phrase *three times* quantifies a verb; hence this sentence instantiates verbal quantification.

Up to a point, nominal and verbal quantification exhibit parallel grammatical properties. Obvious, but still worth noting, is the fact that in both of the preceding sentences, the same numeral, *three*, is used. However, nominal and verbal quantification also differ in many ways; typically, verbal quantification is more highly marked than its nominal counterpart.

Continuous and Discontinuous Quantifiers

A distinct albeit related syntactic classification pertains to the position of the quantifier with respect to the quantified expression, specifically, whether or not the two form a continuous constituent (Gil, 1993; Bach et al., 1995). Sentences (1)–(4) below all instantiate nominal quantification, in which a numeral quantifies an expression referring to an animal;

however, each of the examples exhibits a different syntactic configuration.

(1) HEBREW

raiti	[*šaloš*	arnavot]
see-PAST:1:SG	three-F	rabbit-PL:F

'I saw three rabbits'

(2) TAGALOG

Tatlo	[*ang*	*nakita*	
three	TOP	PAT.TOP:PFV-see	
kong	*baboy*]		
DIR:1:SG-LIG	pig		

'I saw three pigs'
('The pigs seen by me were three')

(3) KUTENAI (Matthew Dryer, p.c.)

hu	[*qă są*	*wu:kati*]	*cupqa*
1:SG	three-PRV	see-IND	deer

'I saw three deer' ('I three-saw deer')

(4) JAPANESE

Watasi	*wa*	*inu*	o
1:SG	TOP	dog	ACC
sanbiki	*mita*		
three-CLF	see-PFV		

'I saw three dogs' ('I saw dogs threely')

In modern Hebrew, (1), as in its English gloss, the quantifier groups with the quantified expression, *šaloš arnavot*, to the exclusion of the remainder of the sentence; in Tagalog, (2), the quantifier *tatlo* stands alone as a sister to the remainder of the sentence, which forms a constituent; in Kutenai, (3), the quantifier occurs in construction with the verb, *qăsă wu:kati*, to the exclusion of the remainder of the sentence; while in Japanese, (4), the quantifier *sanbiki* is a sentential adverb not forming an obvious constituent with any part of the remainder of the sentence.

Constructions (1) and (2) exemplify continuous quantification, in which the quantifier and the quantified expression form a constituent. In contrast, constructions (3) and (4) exemplify discontinuous quantification, in which the quantifier occurs apart from the quantified expression. Examples (1)–(4) above illustrate the distinction between continuous and discontinuous quantification with respect to nominal quantification. In principle, a similar distinction may also be drawn with respect to verbal quantification, though examples of discontinuous verbal quantification are more hard to come by.

Scope and Scopal Quantifiers

When two quantified expressions are present in the same construction, a variety of semantic relations may obtain between the two expressions (Jackendoff, 1971; Gil, 1982b). The following English sentence, containing two numerically quantified NPs, may, at least potentially, be interpreted in any or all of the following four ways:

(5) Three boys saw two girls

(a) 'Each of three boys saw each of two girls' not scope differentiated: strong symmetric.

(b) 'Three boys saw two girls between them' not scope differentiated: weak symmetric.

(c) 'Three boys saw two girls each' scope differentiated: wide scope for *three* boys distributive key: *three boys*; distributive share: *two girls*.

(d) 'Two girls were seen by three boys each' scope differentiated: wide scope for *two girls* distributive key: *two girls*; distributive share: *three boys*.

Interpretations (5a) and (5b) both involve a single set of three boys and a single set of two girls: each of the two NPs has independent reference. These interpretations are accordingly characterized as non-scope-differentiated or symmetric. Interpretations (5c) and (5d) present a more complex picture. In (5c) there is a single set of three boys; however, each of the three boys is associated with a different set of two girls. Thus, while the subject NP has independent reference, the direct-object NP is referentially dependent on the subject NP. In this interpretation, then, the subject NP has scope over the direct-object NP. More precisely, the two NPs are in a relationship of distributivity, with the subject NP as *distributive key*, and the direct-object NP as *distributive share*. In (5d), a mirror-image situation obtains. Here, there is a single set of two girls; however, each of the two girls is associated with a different set of three boys. Accordingly, while the direct-object NP has independent reference, the subject NP is referentially dependent on the direct-object NP; the direct-object NP has scope over the subject NP. Here too then, a relation of distributivity obtains; this time, though, it is the direct-object NP which is the distributive key and the subject NP which is the distributive share.

The above four interpretations are not equally readily available for speakers of English. Specifically, the symmetric interpretations (5a) and (5b) are more easily available than the asymmetric interpretations (5c) and (5d). Moreover, between the latter two interpretations, (5c) with wide scope for the subject NP is more readily available than (5d) with wide scope for the direct-object NP. These preferences are not accidental; rather, they are particular consequences of more general principles governing the assignment of quantifier scope across languages.

Given the general preference for symmetric interpretations, languages typically have, at their disposal, various lexical and morphosyntactic devices whose function is to induce the more marked asymmetric interpretations, when these are required. Consider the following English sentences:

(6) (a) *All* the men carried three suitcases.

(b) *Every* man carried three suitcases.

Sentences (6a) and (6b) differ in the lexical choice of quantifier within the subject NP. Whereas in (6a), with *all*, a variety of scope relationships may obtain between the two NPs, and

the number of suitcases may vary between three in total and three per man, in (6b), with *every*, the subject NP has scope over the direct-object NP, and the suitcases number three per man. Whereas *all*, like *three*, is a simple quantifier, *every* is a *scopal* quantifier, that is to say, a quantifier endowed with an additional denotational component, one that forces a particular scope relationship to obtain between the NP in which it occurs, and some other expression. In particular, it is a distributive-key quantifier, inducing a relationship of distributivity, in which the NP containing the quantifier in question is the distributive key, or element with wide scope (Gil, 1995).

A different kind of scopal quantifier is exemplified by the following pair of Maricopa sentences:

(7) Maricopa

(a) *ʔipač* ʔii *xmokm*
man-PL:NOM stick 3-three-SG-DS
upaavk
3-carry-PL-REAL
'The men carried three sticks'

(b) *ʔipač* *ʔii* *xmokxperm*
man-PL:NOM stick 3-three-SG-DIST.SHARE-DS
upaavk
3-carry-PL-REAL
(i) 'The men carried three sticks each'
(ii) 'The men carried the sticks in threes'

Sentences (7a) and (7b) differ only in the form of the numeral within the direct-object expression. Sentence (7a) contains a simple numeral, *xmok-* 'three,' and is ambiguous in roughly the same ways as its English gloss. In contrast, sentence (7b) contains the same numeral plus the suffix *-xper*, whose effect is to mark the numeral *xmok-* and the expression containing it as distributive share. The ambiguity exhibited by sentence (7b) results from different expressions being selected as the distributive key counterpart. Under interpretation (7b(i)), the subject NP *ʔipač* 'men' is chosen as the distributive key: the sticks accordingly number three per man. Under interpretation (7b(ii)), the verb *upaavk* 'carried' is chosen as the distributive key: here the sticks accordingly number three per carrying. Crosslinguistically, distributive-share numerals are formed by a variety of formal processes, including affixation (as in the above example), periphrasis, reduplication, and suppletion (Gil, 1982a).

Quantifier as a Grammatical Category

A quantifier is primarily a semantic category: an expression is a quantifier only if it bears certain meaning properties. One of the most striking characteristics of quantifiers is the absence of any distinctive shared formal morphosyntactic features, which might justify the positing of a corresponding grammatical category of quantifier. Within languages, different quantifiers often display different grammatical properties. And across languages, the 'same' quantifier may exhibit different morphosyntactic behavior as well. Thus, in terms of their formal properties, quantifiers constitute a heterogeneous collection, exhibiting a great amount of morphological and syntactic diversity.

Looking within individual languages, there is probably no language within which there is a formal grammatical category consisting exactly of all quantifiers but no other expressions. Rather, in most or all languages, different quantifiers exhibit different arrays of grammatical properties, some grouping together with expressions belonging to one category, others patterning together with expressions belonging to some other category, and yet others exhibiting idiosyncratic morphological or syntactic behavior.

Looking across languages, quantifiers with the same meaning often exhibit quite different morphological and syntactic behavior. Examples (1)–(4) above showed how the numeral 'three,' as a nominal quantifier, may occur, in different languages, in a variety of different constructions, exhibiting continuous and discontinuous quantification of various kinds. Even if attention is restricted to the most well-known type, that of continuous NP-internal quantification, as in (l), a great amount of crosslinguistic variation may be observed. In particular, in different languages, nominal quantifiers in attributive NP internal position may resemble, to various degrees, nouns, adjectives, and/or verbs.

Delimitation of Quantification

The discussion in the preceding sections was based on a bipartite definition of quantifiers as 'freestanding expressions' whose meanings 'involve the notion of quantity.' Like many similar definitions, this one is useful, but not unproblematical. Specifically, in addition to prototypical quantifiers such as those discussed above, there are numerous expressions and construction types for which it is difficult to adjudicate whether or not they may appropriately be characterized as quantificational.

The first part of the definition is formal: in order for an expression to be considered as a quantifier, it must be freestanding – a word or a phrase, rather than an affix or some other bound morphological unit. Accordingly, various kinds of clitics, particles, and other intermediate units smaller than words but larger than affixes may provide borderline cases straddling the boundary between what is a quantifier and what is not. The distinction between free and bound forms is what underlies the distinction between quantification and the semantically related grammatical category of *number*. Specifically, whereas quantifiers are freestanding, number markers are bound forms. However, in some instances it may be difficult to adjudicate whether a form associated with a quantificational meaning is free or bound, and hence whether it constitutes an instance of quantification or of number. In order to determine whether forms such as these are quantifiers or number markers, it may be necessary to make use of additional diagnostic criteria distinguishing quantifiers from number markers.

The second part of the definition of quantifier is the obvious semantic condition: its meaning must involve the notion of quantity. While in many instances this is quite straightforward, in other cases, quantificational meanings may shade off gradually into other kinds of meanings not generally considered to be quantificational. One class of expressions related in meaning to

nominal quantifiers are those denoting size and other scalar properties. An important class of expressions related to verbal quantifiers are those marking aspectual categories, such as perfect and progressive. More generally, different quantifiers in different languages may be related to an extremely broad range of nonquantificational concepts, synchronically and/or diachronically.

Abstract

Classical least squares regression may be viewed as a natural way of extending the idea of estimating an unconditional mean parameter to the problem of estimating conditional mean *functions*; the crucial link is the formulation of an optimization problem that encompasses both problems. Likewise, quantile regression offers an extension of univariate quantile estimation to estimation of conditional quantile functions via an optimization of a piecewise linear objective function in the residuals. Median regression is a special case and minimizes the sum of absolute residuals, an idea introduced by Boscovich in the eighteenth century.

The asymptotic theory of quantile regression closely parallels the theory of the univariate sample quantiles. Computation of quantile regression estimators may be formulated as a linear programing problem and efficiently solved by simplex or barrier methods. A close link to rank-based inference has been forged from the theory of the dual regression quantile process, or regression rankscore process.

Quantile regression is a statistical technique intended to estimate, and conduct inference about, conditional quantile functions. Just as classical, linear regression methods based on minimizing sums of squared residuals enable one to estimate models for conditional mean functions, quantile regression methods offer a mechanism for estimating models for the conditional median function, and the full range of other conditional quantile functions. By supplementing the estimation of conditional mean functions with techniques for estimating an entire family of conditional quantile functions, quantile regression is capable of providing a more complete statistical analysis of the stochastic relationships among random variables.

Quantile regression has been used in a broad range of application settings. Reference growth curves for childrens' height and weight have a long history in pediatric medicine; quantile regression methods may be used to estimate upper and lower quantile reference curves as a function of age, sex, and other covariates without imposing stringent parametric assumptions on the relationships among these curves. See, e.g., Wei et al. (2005). Quantile regression methods have been widely used in economics to study determinants of wages, discrimination effects, and trends in income inequality. Several recent studies have modeled the performance of public school students on standardized exams as a function of socioeconomic characteristics like their parents' income and educational attainment, and policy variables like class size, school expenditures, and teacher qualifications. It seems rather implausible that such covariate effects should all act so as to shift the entire distribution of test results by a fixed amount. It is of obvious interest to know whether policy interventions alter performance of the strongest students in the same way that weaker students are affected. Such questions are naturally investigated within the quantile regression framework.

In ecology, theory often suggests how observable covariates affect limiting sustainable population sizes, and quantile regression has been used to directly estimate models for upper quantiles of the conditional distribution rather than inferring such relationships from models based on conditional central tendency. In survival analysis, and event history analysis more generally, there is often also a desire to focus attention on particular segments of the conditional distribution, for example, survival prospects of the oldest-old, without the imposition of global distributional assumptions.

Quantiles, Ranks, and Optimization

We say that a student scores at the τth quantile of a standardized exam, if he performs *better* than the proportion τ, and *worse* than the proportion $(1-\tau)$, of the reference group of students. Thus, half of the students perform better than the median student, and half perform worse. Similarly, the quartiles divide the population into four segments with equal proportions of the population in each segment. The quintiles divide the population into five equal segments; the deciles into 10 equal parts. The quantile, or percentile, refers to the general case.

More formally, any real valued random variable, Y, may be characterized by its distribution function,

$$F(y) = \text{Prob}(Y \le y)$$

while for any $0 < \tau < 1$,

$$Q(\tau) = \inf\{y : F(y) \ge \tau\}$$

is called the τth quantile of X. The median, $Q(1/2)$, plays the central role. Like the distribution function, the quantile function provides a complete characterization of the random variable, Y.

The quantiles may be formulated as the solution to a simple optimization problem. For any $0 < \tau < 1$, define the piecewise linear 'check function,' $\rho_\tau(u) = u(\tau - I(u < 0))$ illustrated in Figure 1. Minimizing the expectation of $\rho_\tau(Y - \xi)$ with respect to ξ yields solutions, $\xi(\tau)$, the smallest of which is $Q(\tau)$ defined above.

The sample analogue of $Q(\tau)$, based on a random sample, $\{y_1, \ldots, y_n\}$, of Y's, is called the τth *sample* quantile, and may be found by solving,

$$\min_{\xi \in R} \sum_{i=1}^{n} \rho_\tau(y_i - \xi)$$

Figure 1 Quantile regression ρ function.

While it is more common to define the sample quantiles in terms of the order statistics, $y_{(1)} \leq y_{(2)} \leq \ldots \leq y_{(n)}$, constituting a sorted rearrangement of the original sample, their formulation as a minimization problem has the advantage that it yields a natural generalization of the quantiles to the regression context.

Just as the idea of estimating the unconditional mean, viewed as the minimizer,

$$\widehat{\mu} = \text{argmin}_{\mu \in \mathbb{R}} \sum (y_i - \mu)^2$$

can be extended to estimation of the linear conditional mean function $E(Y|X = x) = x'\beta$ by solving,

$$\widehat{\beta} = \text{argmin}_{\beta \in \mathbb{R}^p} \sum \left(y_i - x_i'\beta\right)^2$$

the linear conditional quantile function, $Q_Y(\tau|X = x) = x_i'\beta(\tau)$, can be estimated by solving,

$$\widehat{\beta}(\tau) = \text{argmin}_{\beta \in \mathbb{R}^p} \sum \rho_\tau(y_i - x'\beta)$$

The median case, $\tau = 1/2$, which is equivalent to minimizing the sum of *absolute* values of the residuals has a long history. In the mid-eighteenth century, Boscovich proposed estimating a bivariate linear model for the ellipticity of the earth by minimizing the sum of absolute values of residuals subject to the condition that the mean residual took the value zero. Subsequent work by Laplace characterized Boscovich's estimate of the slope parameter as a weighted median and derived its asymptotic distribution. F.Y. Edgeworth seems to have been the first to suggest a general formulation of median regression involving a multivariate vector of explanatory variables, a technique he called the 'plural median.' The extension to quantiles other than the median was introduced in Koenker and Bassett (1978).

An Example

To illustrate the approach, we may consider an analysis of a simple first-order autoregressive model for maximum daily temperature in Melbourne, Australia. The data are taken from Hyndman et al. (1996). In **Figure 2**, we provide a scatter plot of

Figure 2 Melbourne maximum daily temperature: the plot illustrates 10 years of daily maximum temperature data (in degrees centigrade) for Melbourne, Australia as an AR(1) scatterplot. The data are scattered around the (dashed) 45° line suggesting that today is roughly similar to yesterday. Superimposed on the scatterplot are estimated conditional quantile functions for the quantiles $\tau \in \{0.05, 0.10, \ldots, 0.95\}$. Note that when yesterday's temperature is high the spacing between adjacent quantile curves is narrower around the 45° line and at about 20 °C than it is in the intermediate region. This suggests bimodality of the conditional density in the summer.

10 years of daily temperature data: today's maximum daily temperature is plotted against yesterday's maximum. Our first observation from the plot is that there is a strong tendency for data to cluster along the (dashed) 45° line implying that with high probability today's maximum is near yesterday's maximum. But closer examination of the plot reveals that this impression is based primarily on the left side of the plot, where the central tendency of the scatter follows the 45° line very closely. On the right side, however, corresponding to summer conditions, the pattern is more complicated. There, it appears that *either* there is another hot day, falling again along the 45° line, *or* there is a dramatic cooling off. But a mild cooling off appears to be more rare. In the language of conditional densities, if today is hot, tomorrow's temperature appears to be bimodal with one mode roughly centered at today's maximum, and the other mode centered at about 20°.

Several estimated quantile regression curves have been superimposed on the scatterplot. Each curve is specified as a linear B-spline. Under winter conditions these curves are bunched around the 45° line, however, in the summer it appears that the upper quantile curves are bunched around the 45° line and around 20°. In the intermediate temperatures, the spacing of the quantile curves is somewhat greater indicating lower probability of this temperature range. This impression is strengthened by considering a sequence of density plots based on the quantile regression estimates. Given a family of reasonably densely spaced estimated conditional quantile functions, it is straightforward to estimate the conditional density of the response at

various values of the conditioning covariate. In Figure 3, we illustrate this approach with several of density estimates based on the Melbourne data. Conditioning on a low previous day temperature we see a nice unimodal conditional density for the following day's maximum temperature, but as the previous day's temperature increases we see a tendency for the lower tail to lengthen and eventually for very warm summer days we see a clearly bimodal density. In this example, the classical regression assumption that the covariates affect only the location of the response distribution, but not its scale or shape, is clearly violated.

Interpretation of Quantile Regression

Least squares estimation of mean regression models asks the question, 'How does the conditional mean of Y depend on the covariates X?' Quantile regression asks this question at each quantile of the conditional distribution enabling one to obtain a more complete description of how the conditional distribution of Y given $X = x$ depends on x. Rather than assuming that covariates shift only the location or scale of the conditional distribution, quantile regression methods enable one to explore potential effects on the shape of the distribution as well. Thus, for example, the effect of a job training program on the length of participants' current unemployment spell might be to lengthen the shortest spells while dramatically reducing the probability of very long spells. The mean treatment effect in such circumstances might be small, but the treatment effect on the shape of the distribution of unemployment durations could, nevertheless, be quite significant.

Quantile Treatment Effects

The simplest formulation of quantile regression is the two-sample treatment–control model. In place of the classical Fisherian experimental design model in which the treatment induces a simple location shift of the response distribution, Lehmann (1974) proposed the following general model of treatment response:

> *Suppose* the treatment adds the amount $\Delta(x)$ when the response of the untreated subject would be x. Then the distribution G of the treatment responses is that of the random variable $X + \Delta(X)$ where X is distributed according to F.

Special cases obviously include the location shift model, $\Delta(X) = \Delta_0$, and the scale shift model, $\Delta(X) = \Delta_0 X$, but the general case is natural within the quantile regression paradigm.

Doksum (1974) shows that if $\Delta(x)$ is defined as the 'horizontal distance' between F and G at x, so

$$F(x) = G(x + \Delta(x))$$

then $\Delta(x)$ is uniquely defined and can be expressed as

$$\Delta(x) = G^{-1}(F(x)) - x$$

Figure 3 Conditional density estimates of today's maximum temperature for several values of yesterday's maximum temperature based on the Melbourne data: these density estimates are based on a kernel smoothing of the conditional quantile estimates as illustrated in the previous figure using 99 distinct quantiles. Note that temperature is bimodal when yesterday was hot.

Changing variables so $\tau = F(x)$ one may define the *quantile treatment effect*,

$$\delta(\tau) = \Delta\left(F^{-1}(\tau)\right) = G^{-1}(\tau) - F^{-1}(\tau)$$

In the two-sample setting, this quantity is naturally estimable by

$$\widehat{\delta}(\tau) = \widehat{G}_n^{-1}(\tau) - \widehat{F}_m^{-1}(\tau)$$

where G_n and F_m denote the empirical distribution functions of the treatment and control observations, based on n and m observations, respectively.

Formulating the quantile regression model for the binary treatment problem as,

$$Q_{Yi}(\tau|D_i) = \alpha(\tau) + \delta(\tau)D_i$$

where D_i denotes the treatment indicator, with $D_i = 1$ indicating treatment, $D_i = 0$, control, then the quantile treatment effect can be estimated by solving,

$$\left(\widehat{\alpha}(\tau), \widehat{\delta}(\tau)\right)' = \operatorname{argmin} \sum_{i=1}^{n} \rho_\tau(y_i - \alpha - \delta D_i)$$

The solution $(\widehat{\alpha}(\tau), \widehat{\delta}(\tau))'$ yields $\widehat{\alpha}(\tau) = \widehat{F}_n^{-1}(\tau)$, corresponding to the control sample, and

$$\widehat{\delta}(\tau) = \widehat{G}_n^{-1}(\tau) - \widehat{F}_n^{-1}(\tau)$$

Doksum suggests that one may interpret control subjects in terms of a latent characteristic: for example, in survival analysis applications, a control subject may be called frail if he is prone to die at an early age, and robust if he is prone to die at an advanced age. This latent characteristic is thus implicitly indexed by τ, the quantile of the survival distribution at which the subject would appear if untreated, i.e., $(Y_i|D_i = 0) = \alpha(\tau)$. And the treatment, under the Lehmann model, is assumed to alter the subjects control response, $\alpha(\tau)$, making it $\alpha(\tau) + \delta(\tau)$ under the treatment. If the latent characteristic, say, the propensity for longevity, were observable *ex ante*, then one could view the treatment effect $\delta(\tau)$ as an explicit interaction with this observable variable. In the absence of such an observable variable, however, the quantile treatment effect may be regarded as a natural measure of the treatment response.

It may be noted that the quantile treatment effect is intimately tied to the two-sample QQ-plot, which has a long history as a graphical diagnostic device. The function $\widehat{\Delta}(x) = G_n^{-1}(F_m(x)) - x$ is exactly what is plotted in the traditional two-sample QQ-plot. If F and G are identical then the function $G_n^{-1}(F_m(x))$ will lie along the 45° line; if they differ only by a location scale shift, then $G_n^{-1}(F_m(x))$ will lie along another line with intercept and slope determined by the location and scale shift, respectively. Quantile regression may be seen as a means of extending the two-sample QQ-plot and related methods to general regression settings with continuous covariates.

When the treatment variable takes more than two values, the Lehmann–Doksum quantile treatment effect requires only minor reinterpretation. If the treatment variable is continuous as, for example, in dose–response studies, then it is natural to consider the assumption that its effect is linear, and write,

$$Q_{Yi}(\tau|x_i) = \alpha(\tau) + \beta(\tau)x_i$$

We assume thereby that the treatment effect, $\beta(\tau)$, of changing x from x_0 to $x_0 + 1$ is the same as the treatment effect of an alteration of x from x_1 to $x_1 + 1$. Note that this notion of the quantile treatment effect measures, for each τ, the change in the response required to stay on the τth conditional quantile function. As in the Melbourne example, nonlinear conditional quantile functions can be estimated by simply expanding covariates in spline basis functions.

Transformation Equivariance of Quantile Regression

An important property of the quantile regression model is that, for any monotone function, $h(\cdot)$,

$$Q_{h(T)}(\tau|x) = h(Q_T(\tau|x))$$

This follows immediately from observing that

$$\text{prob}(T < t|x) = \text{prob}(h(T) < h(t)|x)$$

This equivariance to monotone transformations of the conditional quantile function is a crucial feature, allowing one to decouple the potentially conflicting objectives of transformations of the response variable. This equivariance property is in direct contrast to the inherent conflicts in estimating transformation models for conditional mean relationships. Since, in general, $E(h(T)|x) \neq h(E(T|x))$ the transformation alters in a fundamental way what is being estimated in ordinary least squares regression.

A particularly important application of this equivariance result, and one that has proven extremely influential in the econometric application of quantile regression, involves censoring of the observed response variable. The simplest model of censoring may be formulated as follows. Let y_i^* denote a latent (unobservable) response assumed to be generated from the linear model

$$y_i^* = x_i'\beta + u_i \quad i = 1, \ldots, n$$

with $\{u_i\}$ independent and identically distributed (iid) from distribution function F. Due to censoring, the y_i^*'s are not observed directly, but instead one observe

$$y_i = \max\{0, y_i^*\}$$

Powell (1986) noted that the equivariance of the quantiles to monotone transformations implied that in this model the conditional quantile functions of the response depended only on the censoring point, but were independent of F. Formally, the τth conditional quantile function of the observed response, y_i, in this model may be expressed as

$$Q_i(\tau|x_i) = \max\{0, x_i'\beta + F_u^{-1}(\tau)\}$$

The parameters of the conditional quantile functions may now be estimated by solving

$$\min_b \sum_{i=1}^{n} \rho_\tau\left(y_i - \max\{0, x_i'b\}\right)$$

where it is assumed that the design vectors x_i, contain an intercept to absorb the additive effect of $F_u^{-1}(\tau)$. This model is computationally somewhat more demanding than conventional linear quantile regression because it is nonlinear in parameters.

Robustness

Robustness to distributional assumptions is an important consideration throughout statistics, so it is important to emphasize that quantile regression inherits certain robustness properties of the ordinary sample quantiles. The estimates and the associated inference apparatus have an inherent distribution-free character since quantile estimation is influenced only by the local behavior of the conditional distribution of the response near the specified quantile. Given a solution $\widehat{\beta}(\tau)$, based on observations, $\{y, X\}$, as long as one does not alter the sign of the residuals, *any* of the y observations may be arbitrary altered without altering the initial solution. Given the x's only the signs of the residuals matter in determining the quantile regression estimates, and thus outlying responses influence the fit in so far as they are either above or below the fitted hyperplane, but how far above or below is irrelevant. While quantile regression estimates are inherently robust to contamination of the response observations, they can be quite sensitive to contamination of the design observations, $\{x_i\}$. Several proposals have been made to ameliorate this effect.

Computational Aspects of Quantile Regression

Although it was recognized by a number of early authors, including Gauss, that solutions to the median regression problem were characterized by an exact fit through p sample observations when p linear parameters are estimated, no effective algorithm arose until the development of linear programing in the 1940s. It was then quickly recognized that the median regression problem could be formulated as a linear program, and the simplex method employed to solve it. The algorithm of Barrodale and Roberts (1974) provided the first efficient implementation specifically designed for median regression and is still widely used in statistical software. It can be concisely described as follows. At each step, we have a trial set of p 'basic observations' whose exact fit may constitute a solution. We compute the directional derivative of the objective function in each of the $2p$ directions that correspond to removing one of the current basic observations, and taking either a positive or negative step. If none of these directional derivatives are negative the solution has been found, otherwise one chooses the most negative, the direction of steepest descent, and goes in that direction until the objective function ceases to decrease. This one dimensional search can be formulated as a problem of finding the solution to a scalar weighted quantile problem. Having chosen the step length, we have in effect determined a new observation to enter the basic set, a simplex pivot occurs to update the current solution, and the iteration continues.

This modified simplex strategy is highly effective on problems with a modest number of observations, achieving speeds comparable to the corresponding least squares solutions. But for larger problems with, say $n > 100\,000$ observations, the simplex approach eventually becomes considerably slower than least squares. For large problems recent development of interior point methods for linear programing problems are highly effective. Portnoy and Koenker (1997) describe an approach that combines some statistical preprocessing with interior point methods and achieves comparable performance to least squares solutions even in very large problems.

An important feature of the linear programing formulation of quantile regression is that the entire range of solutions for $\tau \in (0, 1)$ can be efficiently computed by parametric programing.

At any solution $\widehat{\beta}(\tau_0)$ there is an interval of τ's over which this solution remains optimal, it is straightforward to compute the endpoints of this interval, and thus one can solve iteratively for the entire sample path $\widehat{\beta}(\tau)$ by making one simplex pivot at each of the endpoints of these intervals.

Statistical Inference for Quantile Regression

The asymptotic behavior of the quantile regression process $\{\widehat{\beta}(\tau) : \tau \in (0, 1)\}$ closely parallels the theory of ordinary sample quantiles in the one sample problem. Koenker and Bassett (1978) show that in the classical linear model,

$$y_i = x_i\beta + u_i$$

with u_i iid from *df* F, with density $f(u) > 0$ on its support $\{u|0 < F(u) < 1\}$, the joint distribution of $\sqrt{n}(\widehat{\beta}_n(\tau_i) - \beta(\tau))_{i-1}^m$ is asymptotically normal with mean 0 and covariance matrix $\Omega \otimes D^{-1}$. Here $\beta(\tau) = \beta + F_u^{-1}(\tau)e_1$, $e_1 = (1, 0, \ldots, 0)'$, $x_{1i} \equiv 1, n^{-1}\sum x_i x_i' \to D$, a positive definite matrix, and

$$\Omega = \left(w_{ij} = \left(\min\{\tau_i, \tau_j\} - \tau_i\tau_j\right)\right) / \left(f\left(F^{-1}(\tau_i)\right) f\left(F^{-1}(\tau_j)\right)\right)$$

When the response is conditionally independent over i, but not identically distributed, the asymptotic covariance matrix of $\xi(\tau) = \sqrt{n}(\widehat{\beta}(\tau) - \beta(\tau))$ is somewhat more complicated. Let

$$\xi_i(\tau) = x_i\beta(\tau)$$

denote the conditional quantile function of y given x_i, and $f_i(\cdot)$ the corresponding conditional density, and define,

$$J_n(\tau_1, \tau_2) = (\min\{\tau_1, \tau_2\} - \tau_1\tau_2)n^{-1}\sum_{i=1}^{n} x_i x_i'$$

and

$$H_n(\tau) = n^{-1}\sum x_i x_i' f_i(\xi_i(\tau))$$

Under mild regularity conditions on the $\{f_i\}$'s and $\{x_i\}$'s, we have joint asymptotic normality for vectors $(\xi(\tau_i), \ldots, \xi(\tau_m))$ with mean zero and covariance matrix

$$V_n = \left(H_n(\tau_i)^{-1} J_n(\tau_i, \tau_j) H_n(\tau_j)^{-1}\right)_{i=1}^m$$

An important link to the classical theory of rank tests was made by Gutenbrunner and Jurečková (1992), who showed that the rankscore functions of Hájek and Šidák (1967) could be viewed as a special case of a more general formulation for the linear quantile regression model. The formal dual of the quantile regression linear programing problem may be expressed as,

$$\max\{y'a | X'a = (1 - \tau)X'1, \ a \in [0, 1]^n\}$$

The dual solution $\widehat{a}(\tau)$ reduces to the Hájek and Šidák rankscore process when the design matrix, X, takes the simple form of an n vector of ones. The regression rankscore process $\widehat{a}(\tau)$ behaves asymptotically much like the classical univariate

rankscore process, and thus offers a way to extend many rank-based inference procedures to the more general regression context.

Extensions and Future Developments

There is considerable scope for further development of quantile regression methods. Applications to survival analysis and time-series modeling seem particularly attractive, where censoring and recursive estimation pose, respectively, interesting challenges. Portnoy (2003) and Peng and Huang (2014) provide analogues of the Kaplan–Meier and Nelson–Aalan estimators for accelerated failure time type models. This work generalizes Powell's approach to fixed censoring to handle conventional random censoring and their promising extensions to competing risk and recurrent events models.

Model selection and applications to high dimensional data have also attracted considerable interest. This is natural given the close connection the lasso (ℓ_1, total variation) penalty methods that have proven to be highly influential throughout statistics, see, e.g., Belloni and Chernozhukov (2011) and Zou and Yuan (2008).

Nonparametric estimation of conditional quantile functions has developed very rapidly: Chaudhuri (1991) introduced local polynomial methods, Koenker et al. (1994) suggested total variation penalty methods, Koenker (2011) provides an overview of this literature. There is an emerging literature on instrumental variable methods for quantile regression for models with endogenous covariate effects. Building on early work of Chernozhukov and Hansen (2005) and Chesher (2003), this work also has implications for errors in variables and missing data methods for quantile regression, Wei and Carroll (2009).

There is a growing literature on time-series applications of quantile regression; Koenker and Xiao (2004) describe some results on quantile autoregression models, and there is considerable work on stochastic volatility models and density forecasting primarily for financial applications. Frequency domain methods have also been considered in work by Li (2012) and Hagemann (2011). Longitudinal data analysis has also received considerable recent attention, see, e.g., Koenker (2004) and Galvao, Jr. (2011).

Quantile regression for discrete response models remains a serious challenge. Machado and Silva (2005) have proposed convenient methods for count data. For binary response, Kordas (2014) has extended the Manski (1975) maximum score estimator, but computational issues remain an impediment.

There is no general agreement about how to generalize univariate quantiles to multivariate settings, but this has perhaps encouraged a variety of new proposals, see, e.g., Wei (2008), Kong and Mizera (2012), and Hallin et al. (2010) among others.

Conclusion

Classical least squares regression may be viewed as a natural way of extending the idea of estimating an unconditional mean parameter to the problem of estimating conditional mean *functions*; the crucial step is the formulation of an optimization problem that encompasses both problems. Likewise, quantile regression offers an extension of univariate quantile estimation to estimation of conditional quantile functions via an optimization of a piecewise linear objective function in the residuals. Median regression minimizes the sum of absolute residuals, an idea introduced by Boscovich in the eighteenth century.

The asymptotic theory of quantile regression closely parallels the theory of the univariate sample quantiles; computation of quantile regression estimators may be formulated as a linear programing problem and efficiently solved by simplex or barrier methods. A close link to rank-based inference has been forged from the theory of the dual regression quantile process, or regression rankscore process.

Nontechnical introductions to quantile regression are provided by Cade and Noon (2003), Hao and Naiman (2007), and Koenker and Hallock (2001) from the perspective of ecology, sociology, and economics, respectively. A more complete introduction is provided by the monograph of Koenker (2005). Most of the major statistical computing languages now include some capabilities for quantile regression estimation and inference. The quantile regression package *quantreg* for the R language is available from the CRAN archive at http://cran.r-project.org. Stata provides some limited quantile regression estimation and inference functions. SAS also offers some facilities for quantile regression.

Abstract

Quantitative cross-national comparisons usually are based on smaller *N*'s. This implies that theory needs to be stronger and that counterfactuals need to be made explicit. Bayesian estimation is, in this situation, an attractive possibility. Because dependent variables are often categorical or limited, it is often preferable to use nonlinear models, like logit and probit. Selection bias is potentially acute due to nonrandom sampling. This is a problem of identification that usually cannot be overcome by quasi-experimental designs. It calls, again, for strong counterfactual thinking. Cross-national comparisons often cannot assume independence between observations on a variable (nations form 'families'), and this provokes biased coefficients and likely heteroskadisticity. Finally, the article examines the endogeneity problem (*X* is influenced by *Y*, or both jointly by an unobserved *Z*) which is potentially serious in cross-national comparisons because the meaning of a variable is embedded in the nation's entire history. The bias can derive from variable omission in which case correction calls for added controls. The article also examines the tradeoffs between large-*N* and smaller-*N* comparisons in terms of generalization and context, and stresses the need for stronger theory the smaller the number of cases being sampled.

The Main Challenges of Quantitative Nation Comparisons

Quantitative cross-national comparisons have become an important feature of all the social sciences. Their popularity has been spurred, in part, by the increasing availability of good data for a growing number of countries and, in part, by the diffusion of statistical skills among researchers. There are many constraints and potential pitfalls involved in cross-national statistical analyses, and these will be the main theme of this article. But this research strategy has, regardless, proven itself of great scientific value. It has, above all, helped highlight how fundamental many international variations are, thus, providing a powerful check against parochialism and unwarranted generalizations. Quantitative macrocomparisons have also proven themselves eminently useful in testing the validity of core theoretical assumptions, such as the convergence thesis that has long dominated development and modernization theory in political science and sociology especially.

Quantitative nation comparisons will, however, inevitably face a number of tradeoffs; some more serious than others. One is that the capacity for broader generalization that quantification permits is bought at the price of less attention to the contextual reality of individual nations. The uniqueness of a nation's culture, historical heritage, and endemic logic is lost easily when all we actually observe are a few indicators. Moreover, these indicators may mean somewhat different things in the unique context of specific countries (Ragin, 1987). Scholars are frequently quite sensitive to this issue and so attempt to embed their statistical analyses within the histories and social uniqueness of the countries being studied. Also, as Ragin (1994) argues and empirically demonstrates, Boolean analysis can help overcome this dilemma by enabling us to build conjunctural models with very few cases and to analyze nonevents. But the approach is somewhat circumscribed. It needs to be guided by strong theory and background knowledge, its applicability is limited to relatively few cases, and it may be biased in favor of corroborating nonadditive, conjunctural models (Ragin et al., 2003).

A second constraint has to do with the often limited number of observations available. This is especially true of studies of advanced (OECD) democracies where the *N* rarely exceeds 25. In broader worldwide comparisons, however, the *N* approaches 200. Many researchers attempt to supplement the paucity of nations by collecting longitudinal data on each nation, as with pooled cross-sectional and time series analyses. A 20-year time series for 20 countries yields 400 observations; a 20-year time series for 200 nations yields 4000. As ever, longer data series for individual countries become available, the small *N* problem will gradually diminish.

Small samples do not necessarily pose problems of statistical inference, especially when the substantive theory is strong. They do, however, limit what statistical tools can be brought to bear. Fearon (1991) argues that the smaller the sample size, the greater is the need to make counterfactuals explicit – in other words, to tighten the theoretical formulation about the precise conditions that will (or will not) produce an outcome. Vague theory implies uncertainty about the number of contending explanations (which can grow very large) and about their mutual relationship within a causal order. The consequences of this include causal misspecification, multicollinearity and large error terms. The last two of these can only be managed by having more observations. Without them, estimations are likely to yield results that are not robust. The less ambiguous the theory, the less the need for large *N*'s. Small *N*'s are, therefore, an especially acute problem in disciplines without a firm theoretical architecture, like sociology or political science. Western (1998a) argues that Bayesian estimation, by allowing for greater uncertainty, produces more robust results when *N*'s are few, theory vague, and explanations are many.

Small *N*'s can even hold advantages, because a limited nation sample implies that the researcher can gain more easily maximum advantage from diagnostic scrutiny of the residual plots. A set of systematic outliers, for example, can be easily

identified in terms of their nationhood, and any good comparativist should be able to pin down what variable(s) drives their deviance from the fitted regression line. Diagnostics on small samples can approach the advantages of in-depth case studies.

The constraints imposed by small samples are generally well known to researchers. There are additional problems inherent in quantitative national comparisons that are both more generic and potentially more serious, but also less recognized. Chief among these are issues related to qualitative and limited dependent variables, the potential for selection bias, possible lack of independence between observations and, finally, the question of endogeneity of variables.

Qualitative and Limited Dependent Variables

Many dependent variables in cross-national research are either qualitative (assuming discrete values) or limited (they assume continuous values within some range). The choice whether to measure a variable in a qualitative or continuous way is often controversial. Bollen and Jackman (1989), for example, argue that difficulties in classifying some political regimes speak in favor of using continuous scales because 'dichotomizing democracy blurs distinctions between borderline cases.' In contrast, Przeworski et al. (2000) prefer to treat regimes dichotomously or multinomially.

When the dependent variable is either qualitative or limited, we need to use nonlinear models. Whether we give political regimes the values of 0–1 (as do Przeworski et al., 2000) or 1–100 (as does Bollen, 1980), it remains that the value on the dependent variable cannot exceed its maximum when the independent variable(s) tend to infinity, and it cannot fall below its minimum when these variables tend to infinity. Linear models, at best, can provide an approximation within some range of the independent variables.

The standard model when the dependent variable is multinomial is

$$\Pr(Y = j, X = x) = F(x) \qquad [1]$$

where $j = 0, 1, \ldots, J - 1$ and F is the cumulative distribution function. Since such models are covered by any standard textbook we need not present them here. Such models can be applied to panel data unless the number of repeated observations is large.

'Event history analysis' is one particular class of nonlinear models applied in cross-national research. In such models the dependent variable is an event, such as a revolution, regime transition, or a policy adoption. The general model is

$$\Pr(Y(t + \mathrm{d}t) = j) = f(y(t), x(t)), \mathrm{d}t0 \qquad [2]$$

Most often, such models can be conveniently estimated as

$$\log S(t) = \log(1 - F(t)) \qquad [3]$$

where $S(t)$ is the survival function, or the probability that an event lasts beyond time t, and $F(t)$ is the cdf.

For dichotomous dependent variables, logit and probit give very similar results. For multinomial variables, it is often assumed that the errors are independent across the values of the dependent variable, which leads to a logit specification. But this implies a strong assumption, namely the irrelevance of independent alternatives that rarely holds in practice. Multinomial probit, in turn, requires computing multiple integrals, which was until recently computationally expensive. Alternatives would be semi- and nonparametric methods.

The distributions that are commonly used in estimating survival models include the exponential, Weibul, logistic, and Poisson distributions. But, except for the Weibul and exponential, it is very difficult to distinguish statistically between such distributions.

Methods for studying qualitative dependent variables are now standard textbook fare, but what warrants emphasis is that the traditional distinction between 'qualitative' and 'quantitative' research is becoming increasingly obsolete. Phenomena such as social revolutions may be rare, but this just means they occur with a low probability. They can, nevertheless, be studied systematically using maximum likelihood methods.

The Problem of Selection Bias

In comparative research, we are often interested in the effect of some systemic feature, institution, or policy on some outcome. Examples include the effect of labor market institutions on unemployment, the effect of political regimes on economic growth, or the effect of electoral rules on the number of political parties.

In such cases, the question is how some feature of X affects some outcomes Y in the presence of conditions Z, or PR (Y, X, Z), where the hypothesis is that $y = f(x)$. The generic problem is how to isolate the effects of X and Z on Y.

If sampling is exogenous (i.e., the probability of observing any y is independent of z), the $pr(Y = yz) = pr(y)$, and standard statistical methods can be used. But if $pr(Y = yz)$ is different under different conditions Z, sampling is endogenous and the assumptions of the standard statistical model are violated.

To exemplify the problem: Suppose we want to know the impact of political regimes on economic growth. We observe Chile in 1985 (Z), which was a dictatorship (X), in which case per capita income declined at the rate of $Y = -2.26$. To assess the effect of political regimes, we need to know what would have been the rate of growth (Y) in Chile had it been a democracy. This cannot be answered with the available observations because Chile in 1985 was indeed a dictatorship. The comparativist in such a case would proceed quasi-experimentally, and look for a case that matches Chile in all aspects except authoritarianism. In this way one would compare an authoritarian with a democratic 'Chile.'

But what if Chile's status as a dictatorship in 1985 was due to some factors that also affected its economic performance? This could be because growth itself influences the survival of regimes; a country's level of development may be associated both with regime selection and growth; some unobservable factors (say 'enlightened leadership' or, perhaps, measurement error) may be common to both variables. Whatever the underlying selection mechanism, the basic consequence is that there will be cases without a match, and this implies that our inferences will be biased.

The problem raised by nonrandom selection is how to make inferences from what we observe to what we do not. It is

a problem of identification. For what do we know when we observe Chile as a dictatorship in 1985? We observe the fact that, given conditions Z, the Chilean regime (X) is a dictatorship. We also know its rate of economic growth, given that it is a dictatorship under conditions Z. We do not observe, however, its rate of growth as a democracy under conditions Z. The issue is one of counterfactual observations: the rate of growth that an observation with $Z = zi$, observed under dictatorship, would have had under democracy. We do not know what this value is and, hence, we face underidentification.

What we need to know are two distributions, $P(Y = y, x = j, Z)$ and $P(Y = y, x = k, Z)$, and their expected values, where we now think of the possible values of X more generally as j, $k = 0, 1, 2, \ldots, N$. The first is the distribution of Y in the entire population if all cases were observed as dictatorships; the second is the distribution of Y in the entire population if all cases were observed as democracies. Clearly, if we want to know the impact on y of being in states x, we need to determine the difference between these two distributions, conditional on z.

It may seem strange to refer to the 'population' as including unobserved cases. But in order to compare the effects of states x on the performance of an individual case characterized by a zi, we must allow the case to be potentially observable under the full range of X. We observed this case as $X = j$, but must also imagine the possibility that it would have been Xj. We must think in terms of a 'superpopulation' consisting of a continuum of potential cases. The actual sample is then regarded as having been drawn by 'nature' from this superpopulation.

If the actual population is an exogenous sample of the potential one, any multivariate combination (xi, zi) can be drawn with a positive probability. Such exogenous sampling allows us to isolate the effect of x on y given z, that is, to 'control' for z the effects of x on y. If the sample is exogenous, we can 'match' pairs ($xi = j$, zi) and ($xi = k$, zi). But if sampling is endogenous, there will be some cases without a 'match': some of the xi's will not have support. Where we have nonrandom selection, quasi-experimental comparisons fail regardless of the number of observations.

The methods to correct for selection bias consist of constructing counterfactuals, that is, of filling the unobserved supports of the distribution Y for all X. Following Heckman (1988), when sampling is not random, the regressions $y = f(x, z)$ suffer from omitted variable bias. When such regressions are estimated on the basis of the observed sample, the variable that is omitted is the expected value of the error in the equation that specifies how the observations are selected into the sample.

$$\Pr(x = j) = F(Z) + u \qquad [4]$$

If

$$E(uj\, x = j)\ 0 \qquad [5]$$

then

$$E(uj\, x) = juE(u\, x) \qquad [6]$$

where ju is a regression coefficient of uj on u.

Finally, $E(ux = j) = j$, where the j's are the inverse Mill ratios, or the hazard rates. Since we know that Yj is observed when $x = j$, we can write the expected values in the observed sample as

$$E(yj\, x = j, z) = zj + ju\, j \qquad [7]$$

Note that if this equation is estimated on the basis of the observed sample, the variable j is omitted from the specification.

We can now see why controlling for the variables that enter both into selection and outcome equations may indeed worsen the selection bias. Following Heckman (1988), we distinguish first between selection on observables and on unobservables. Selection on observables occurs when the expected covariance $E(uju\, z)\ 0$, but once the observed variables Z are controlled for it vanishes, so that $E(uju\, z) = 0$. Selection is on unobservables when $E(uju)\ 0$ and $E(uju\, z)\ 0$, which means that controlling for the factors observed by the investigator does not remove the covariance between the errors in the outcome and the selection equations. Now note that the regression coefficient $ju = \mathrm{cov}(uju)/\mathrm{var}(uj)$. If selection is on unobservables, controlling for some variable x in the outcome equation may reduce the error variance uj without equally reducing the covariance uju. Hence, the coefficient on the omitted variable will be larger and the bias will be exacerbated.

In short, the expected values of the observed cases will be biased because they covary with the variable which determines which cases are observed. If selection is exclusively on observables, this bias can be corrected by traditional controlling techniques. But if it is on unobservables, such controls only worsen the bias.

Correcting for selection bias is not uncontroversial. It has been found that corrections for selection are not robust, but are highly sensitive to relatively minor changes in assumptions about distributions (Goldberger, 1983; Robins et al., 2000). Others have found that some estimation methods fail to correct for this bias and may even exacerbate it. As Heckman (1988) argues, the quandary we face is that different methods of correcting for selection bias are robust if there is no bias to begin with; if there is, there is no guarantee that the methods are robust.

The logic of the problem is similar whether we study large or small N's. When de Toqueville concluded that revolutions do not bring about social change, the reason might be that they occur only in countries where it is difficult to change society. Even when $N = 1$, the issue of selection bias does not disappear: The French revolution in 1789 may have been caused by the same conditions that made social change so difficult. It is possible that a revolution in a country where social relations are easier to change would have provoked change. But then a revolution would not have been necessary.

Comparativists who conduct case studies cannot benefit from statistical distributions to generate the counterfactuals. Yet, as in all cases of comparison the problem remains and it should, therefore, be standard practice to ask counterfactual questions of one's case or cases.

The Problem of Independence

Statistical inference must assume that the observations on a variable are independent one of the other. Is country A's

performance truly independent of what happens in country B? Is what happens at $t + 1$ independent of events in t? Usually not, and this implies the need for corrective procedures. In most cases, however, rigorous correction will entail that the *de facto N* (nations or years) diminishes; in some instances, statistical dependency cannot be resolved at all.

Cross-sectional analysis almost invariably assumes that nations and their properties (say budgets or institutions) are independent one of the other. This should not be assumed. We know that the Scandinavian countries have a shared history, deliberately learning from each other through centuries, thus creating similar institutions and path dependencies. The same goes for Austria and Germany, for Belgium and the Netherlands and, arguably, for all the Anglo-Saxon nations. World samples have a similar problem: Japan's long hegemony in East Asia will have influenced Korean society; Confucianism has had a pervasive influence throughout the region. Similar stories are easily told for Latin America and Africa. If the world is a set of nation clusters, the real *N* is not 20-odd OECD countries or 150-odd world nations.

When nations form families, but are treated as if they were all unique and independent, we are likely to get biased coefficients and, very probably, unequal error variance (heteroskadicity). Sweden alone will drive the regression line in just about any welfare state analysis, and when also Denmark and Norway are treated as discrete observations, the bias is multiplied in so far as all three in reality form part of the same political family ('Scandinavia'). Diffusion effects that operate between members of a nation cluster can also result in heteroskadistic disturbance in the cross-section. Such can be corrected by, for example, adding a variable that captures the common underlying property that drives the disturbance (say, a dummy for being 'Scandinavia') but, again, this correction absorbs precious degrees of freedom in a small *N* study and, substantively, amounts to reducing the three nations to one observation.

Lack of independence in a time series is normally taken for granted, since this year's budget or election outcome is almost inevitably related to last year's budget or the previous election. The standard assumption is a first-order (AR1) serial correlation. In comparative research virtually all time series applications are pooled with cross-sections. But, where *N*'s are very small, one may as well simply compare across individual time series estimations, as do Esping-Andersen and Sonnberger (1991). Time series are meant to capture historical process. Yet as Isaac and Griffin (1989) argue, they easily end up being a historical.

Pooling cross-sectional with time series data (panel regressions) has become very widespread, especially in studies of the limited group of advanced (OECD) societies. In many cases, the panel design is chiefly cross-sectional (more nations than years); others are temporally dominated (for a discussion, see Stimson, 1985). Panel models are especially problematic because they can contain simultaneous diachronic and spatial interdependence and, worse, the two may interact. The standard method for correcting contemporaneous error correlation (GLS) applies only where the *t*'s well exceed nations (which is rare). The consequence is that *t*-statistics are overestimated, errors underestimated, and the results may therefore not be robust (Beck and Katz, 1995). The Beck and Katz (1995) procedure can correct for temporal and cross-sectional dependency one at a time, but if the two interact, no solution exists. See also Beck et al. (1998) for an application to maximum likelihood estimation.

Panel models can be based on two types of theoretical justification. One is that events or shocks occur over time that affect the cross-sectional variance. There is, for example, a huge recent literature on the impact of labor market 'rigidities' on unemployment: regulations vary across nations but also across time because of deregulatory legislation (see, for example, Nickell, 1997). Deregulation in a country should produce a break in its time series, and the autocorrelation element will be split into the years preceding and following the break. The second justification, not often exploited, is to interpret autocorrelation as an expression of institutional or policy path dependency. In this instant, the rho must be treated as a variable. The problem, of course, is that the rho is likely to combine theoretically relevant information as well as unknown residual autocorrelation. The researcher can accordingly not avoid including a variable that explicitly measures path dependency.

If we insist on faithful adherence to the real world, panel regressions may require so much correction against dependency that the hard-won additional degrees of freedom that come with a time series are easily eaten up. And how many can truthfully claim that time and country dependencies do not interact? Indeed, most sensible comparativists would assume they do: if nations form part of families it should also be the case that the timing of their shocks, events, or policies is interdependent. Such intractable problems are certainly much more severe in small-*N* comparisons. Here, a marginal difference in measurement, the inclusion or exclusion of one country, the addition or subtraction of a year here or there, or the substitution of one variable for another, can change the entire model.

One alternative is to construct multilevel models which explicitly take into account the possibility that nations may 'cluster' (for an overview, see Gelman and Hill, 2006). Nieuwbeerta and Ultee (1999) have, for example, estimated a three level (nation, time, and individual) model of the impact of class on party choice within the context of nations' social mobility structure. A second alternative, in particular when the dependent variable is categorical, is to exploit the advantages of event history analysis. But, here the time series needs to be quite long considering that theoretically interesting events, such as revolutions, democratization, or even welfare reforms, are far between. In the event history context, analytical priority usually is given to temporal change, which brings it much closer to traditional time series analysis. But rather than having to manipulate autocorrelation, time sequencing (states and events) is actively modeled and thus gains analytic status. For an application to nation comparisons, see, for example, Western (1998b), which also can stand as an exemplar of how to minimize the interdependency problem.

There are two particular cases where the lack of independence among observations simply prohibits adequate estimation. The first, noted above, occurs when time and nation dependencies interact. The second is when 'globalization' penetrates all nations and when many nations (such as the European Union) become subsumed under identical constraints. In this instance, existing cross-national correlations

will strengthen and we may, indeed be moving toward an $N = 1$. Of course, global shocks or European Union membership do not necessarily produce similar effects on the dependent variable across nations or time. If nations' institutional filters differ, so will most likely the impact of a global shock on, say, national unemployment rates. Here we would specify interaction effects, but that would be impossible in a pure cross-section, and extremely difficult in a time series, unless we already know how the lag structure will differ according to institutional variation.

The Endogeneity Problem

All probabilistic statistics require conditional independence, namely that the values of the predictor variables are assigned independently of the dependent variable. The basic problem of endogeneity occurs when the explanans (X) may be influenced by the explanandum (Y) or both may be jointly influenced by an unmeasured third. The endogeneity problem is one aspect of the broader question of selection bias discussed earlier.

The endogeneity issue has been debated intensely within the economic growth literature in terms of the causal relationship between technology and growth. But it applies equally to many fields. For example, comparativists often argue that left power explains welfare state development. But are we certain that left power, itself, is not a function of strong welfare states? Or, equally likely, are both large welfare states and left power just two faces of the same coin, different manifestations of one underlying, yet undefined, phenomenon? Would Sweden have had the same welfare state even without its legendary social democratic tradition? Perhaps, if Sweden's cultural past overdetermines its unique kind of social democracy and social policy. If this kind of endogeneity exists, the true X for Sweden is not left power but a full list of all that is 'Sweden.' The vector of the X's becomes a list of all that is nationally unique.

The endogeneity problem becomes easily intractable in quantitative cross-national research because we observe variables (Y's and X's) that represent part of the reality of the nations we sample. Our variables are in effect a partial reflection of the society under study, and the meaning of a variable score for one nation may not be metrically equivalent to that of another – a weighted left cabinet score of 35 for Denmark and 40 for Sweden probably misrepresents the Danish–Swedish difference if, that is, the two social democracies are two different beasts.

A related, and equally problematic, issue arises in the interpretation of coefficient estimations. In the simple cross-sectional regression, the coefficient for left power, economic development, or for coordinated bargaining can only be interpreted in one way: as a constant, across-the-board effect irrespective of national context. If Denmark had five points more left power, its welfare state should match the Swedish (all else held constant). In fixed-effects panel regressions, the X's are assumed to have an identical impact on Y, irrespective of country. Often we cannot accept such assumptions.

The reason that we cannot is that it is difficult to assume that variables, say a bargaining institution or party power balance, will produce homogenous, monotonically identical, effects across nations for the simple reason that they are embedded in a more complex reality (called nation) which has also given rise to its version of the dependent variable. In this case, the bias remains equally problematic whether we study few or many N's; it will not disappear if we add more nations. Quantitative national comparisons rarely address such endogeneity problems. Studies of labor market or economic performance routinely presume that labor market regulations or bargaining centralization are truly exogenous variables, whose effects on employment is conditionally identical whether it is Germany, Norway, or the United States. The same goes for welfare state comparisons with their belief that demography and left power are fully exogenous and conditionally unitary.

There exist several, not necessarily efficient, ways of correcting for the endogeneity bias. If we have some inkling that the bias comes from variable omission, the obvious correction entails the inclusion of additional controls. An example of this kind was Jackman's (1986) argument that Norway's North Sea Oil was overdetermining the results in the Lange and Jarrett (1985) study. Small N studies with strong endogeneity have little capacity to extend the number of potentially necessary controls. A second approach is to limit endogeneity in X by reconceptualizing and, most likely, narrowing Y. The welfare state literature provides a prototypical example: aggregate social expenditure increasingly was replaced by measures of specific welfare state traits.

Controls, no matter how many, will however not resolve the problem under conditions of strong sampling bias. As discussed above, the best solution in such a situation is to concentrate more on the theoretical elaboration of causal relations between variables. If we can assume that our estimations are biased because Y affects the values on X, or because both are jointly attributable to a third underlying force, thinking in counterfactual terms ('would Sweden's welfare state be the same without Sweden's social democracy') will force the researcher to identify more precisely the direct or derived causal connections (Fearon, 1991; Morgan and Winship, 2007). If bias can be assumed to come from the assumption of monotonically homogeneous effects of the X across all nations, the researcher's attention should concentrate on identifying more precisely the conditional mechanisms that are involved in the causal passage from an X to a Y (why and how will a 5-point rise in left power make the Danish welfare state converge with the Swedish?).

Conclusion

The difficulties and tradeoffs that we have synthesized above are intrinsic to all quantitative research, but are often more difficult to deal with in national comparisons because of the inevitability of small samples of countries and of the ways in which nations have developed together in interaction and will continue to do so even more in the future, given globalization. However, the difficulties should not be seen as paralyzing research but rather as stimulating attempts to deal with them. Indeed, in most practical situations today, each of these problems can be dealt with, albeit not perfectly. So, today's partial vices may be the impetus to tomorrow's virtues. Although we may never be able to completely resolve all problems, ongoing trends suggest that our capacity to conduct good quality

research in this field is improving rapidly. For one, the constraints of small *N*'s are diminishing because of rapid progress in data quality and quantity, covering both more years and nations. Second, the field has made great strides in terms of researchers' substantial comparative knowledge of the nations and cultures under study. Hence, our ability to interpret and contextualize statistical findings has greatly strengthened. And this, in turn, is a major precondition for what we believe is the single most effective tool with which to manage the challenges of quantitative comparison: namely, to systematically think in terms of counterfactuals.

Quantitative Linguistics

Abstract

This article surveys a selected variety of statistical methods that are currently used in experimental and observational studies in linguistics. It covers goodness-of-fit tests, monofactorial and multifactorial hypothesis testing methods, and hypothesis-generating techniques. In addition, for the two major sections of significance testing and exploratory methods, the article also discusses a wide range of statistical desiderata, i.e., perspectives and methods whose more widespread recognition or adoption would benefit linguistics as a discipline.

Introduction

Over the last 20 or so years, linguistics has taken a decidedly quantitative turn. While subdisciplines such as phonetics, sociolinguistics, and experimental psycholinguistics have employed statistical methods for a long time, work in most other central subdisciplines – morphology, syntax, semantics, to name but a few – has only done so since about the 1990s. This shift has no doubt been facilitated by a variety of developments.

For example, the predominance of generative linguistics, with its stance that experimental or observational evidence for one's judgments is not really required, has waned and functional, cognitive, and exemplar-usage-based theories have become more widely adopted; since these theories have relied much on empirical data, an increase in the use of statistical tools was a natural by-product of these theoretical developments.

In addition to any major theoretical shifts in linguistics, there are also growing overall tendencies to (1) study linguistic phenomena from quantitative perspectives including, but not limited to, probability theory, information theory, etc. and (2) cross-disciplinary boundaries and, thus, get involved with neighboring disciplines in which statistical modeling has been much more widespread such as psychology, sociology, and communication.

As yet another example, technological progresses – computers with faster processors, more RAM, and larger hard drives as well as the invention of the WWW – have made it much easier to compile and process large(r) corpora and other kinds of 'big data.' Large(r) corpora in turn yield higher frequency data, which cannot be studied by mere eyeballing; so this, too, has led to a burgeoning use of statistics in all areas of linguistics in which corpora are studied.

As a result of these converging trends, quantitative methods in linguistics are now established and constitute a vibrant methodological domain. However, given the ever-evolving nature of the field of statistics and the recency of the more widespread adoption of quantitative methods in linguistics, the latter are also still in a field of flux as best practices are still being developed/established. This article provides an overview of how statistical tools are used in linguistics – given the vastness and diversity of linguistics as well as all the ways in which statistical methods can be used; however, this can only be a highly selective bird's-eye overview. The section 'Hypothesis-Testing Methods' covers quantitative methods that are hypothesis testing in nature, i.e., that return, among other things, *p*-values from significance tests. The section 'Hypothesis-Generating Methods', then, deals with hypothesis-generating approaches, i.e., methods that aim at detecting or hypothesizing structures in data without necessarily testing these for significance. Each of these sections will first provide an overview of what may be considered the state of the art before turning to a variety of desiderata, i.e., methods or developments. The section 'Concluding Remarks' then concludes with a few general developments that linguistics as a discipline would benefit from.

Hypothesis-Testing Methods

Statistical tools that belong to the domain of null-hypothesis significance testing are the most widespread in linguistics. Within this set of tools, one needs to distinguish between *goodness-of-fit tests* and *tests for independence/differences*. The former are concerned with testing whether a characteristics of a particular data set – a mean, a standard deviation, the overall distribution – is different from that of some other data set (e.g., one from a previous study) or a known distribution (e.g., the bell-shaped normal distribution). The latter can be divided up into *monofactorial* and *multifactorial* tests: both involve one *dependent variable* (or response or effect), but the monofactorial designs contain only one *independent variable* (or predictor or cause) whereas multifactorial designs contain more than one independent variable. While not a standard statistical terminology, it has occasionally been didactically useful to distinguish two kinds of multifactoriality; Adopting this distinction, multifactorial$_1$ refers to designs in which multiple independent variables are involved but without interactions, whereas multifactorial$_2$ then refers to designs in which multiple independent variables are involved such that they may interact with each other.

The following sections will survey monofactorial and multifactorial approaches. However, given the fact that no linguistic phenomenon is truly monofactorial in nature and that,

correspondingly, the field has been moving in the direction of multifactorial testing, the emphasis will be on this latter type of approach.

Goodness-of-Fit Tests in Common Use

Nearly all statistical tests can be said to involve one of the following five statistics:

- Distributions
- Frequencies
- Averages (such as means or medians)
- Dispersions (such as standard deviations or interquartile ranges)
- Correlations (such as Pearson's r or Kendall's τ).

Thus, for each of these statistics, goodness-of-fit tests are conceivable. The probably most frequent goodness-of-fit test involves testing distributions, more specifically whether data are normally distributed, i.e., whether a histogram or density plot would result in a symmetric bell-shaped form. This scenario is frequent because many statistical tests require that the data tested exhibit this shape lest their significance tests produce unreliable results. Figure 1 exemplifies this scenario: a researcher may have collected the data represented by the histogram and the dashed density curve and now needs to determine whether the data are sufficiently similar to the heavy normal curve to assert that his data are normally distributed.

However, goodness-of-fit tests are available for the other four statistics, too. An example for frequencies involves testing whether the frequencies with which foreign language learners choose three modal verbs in a gap-filling experiment differ significantly from native speakers' choices in some prior study. An example for averages involves testing whether foreign language learners' average acceptability judgment for n sentences is significantly different from native speakers' average acceptability judgment in previously studied data. And an example for correlations involves testing whether the correlation between the age of a child and the child's mean length of utterance in morphemes in corpus data is the same as that found for other children from a comparable corpus.

Tests for Independence/Differences in Common Use

The much more frequent kind of statistical scenario involves both dependent and independent variables, and the statistic of the dependent variable is typically one of the five listed above.

Monofactorial Designs

In monofactorial hypothesis tests, one is usually interested in whether the value of the statistic in question of the dependent variable is dependent on the value of the independent variable; put differently, the question is, 'do the values of the independent variable make a difference for those of the dependent variable?' An example for a test for independence/differences of distributions would be the question of whether the similarities of the source words of blends (e.g., *breakfast* and *lunch* for *brunch*) are differently distributed from the similarities of the source words of complex clippings (e.g., *system* and *administrator* for *sysadmin*). If one was *not* interested in whether the average source word similarities are different, but just in the overall distributions of source word similarities – are the more larger values for blends? – then one could run a Kolmogorov–Smirnov test. If one *was* interested in the difference of average source word similarities of blends and complex clippings, then one could perhaps run a t-test for independent samples. If the source word similarities are not normally distributed and have different variances, one could perhaps run a U-test.

An example for a test for independence/differences of dispersions would be the question of whether two groups of subjects – say, native speakers and foreign language learners – exhibit differently variable sentence lengths (because, perhaps, the native speakers' higher competence allows them to exploit longer sentence lengths more for stylistic/expressive means); such a question could, if certain conditions are met, be tested with an F-test for variance homogeneity.

Finally, testing frequencies for independence/differences are often applied to frequency tables such as Table 1. If 100 subjects were asked "at what time does your shop close?" and an additional 100 subjects were asked "what time does your shop close?" one noted the frequencies with which one received the answers "at five o'clock" and "five o'clock," then one could test the resulting Table 1 with a chi-squared test, which would here return a significant result indicating that subjects prefer to use *at* when they were asked with *at*.

The above tests all have in common that the data evaluated are all independent; for example, no subject or no word provides more than one data point. In cases where this is not

Table 1 Fictitious data from a priming experiment

	Answer with at	*Answer without at*	*Totals*
Question with *at*	70	30	100
Question without *at*	45	55	100
Totals	115	85	200

the case, as in when subjects take a test before and after a treatment, alternatives to many of the above tests are available.

Multifactorial Designs

As mentioned above, statistical designs in many subdisciplines of linguistics now do more justice to the fact that linguistic choices are bound to always be affected by multiple causes. As a result, multifactorial approaches are now more common than ever. Most such studies involve different types of regression modeling, which can be considered state of the art at this point:

- *linear modeling*, a type of approach where the predictors can be categorical or numeric and where the dependent variable is numeric. In traditional references, such models may be treated under the headings of ANOVA (analysis of variance) or ANCOVA (analysis of covariance);
- *generalized linear modeling*, a type of approach where the predictors can be categorical or numeric and where the dependent variable can be of different forms: binary, ordinal, categorical/multinomial, or frequencies, which give rise to binary logistic regression, ordinal logistic regression, multinomial/polytomous regression, and Poisson regression respectively. (Strictly speaking, multinomial regression is not a type of generalized linear model, but for simplicity's sake and because it is closely related to a sequence of binary logistic regressions, it is included here in this bullet point.) This process still involves linear modeling after the application of a so-called link function to the dependent variable (which makes sure that the model generates only sensible predictions, e.g., no negative values are predicted for frequencies).

Regression analyses are usually conceptualized as shown in (1) and (2) using an example where a constructional choice by a speaker for an *of*- or an *s*-genitive (will the speaker say *the nut of the squirrel* or *the squirrel's nut*?) may be modeled as a function of the animacy of the possessor (*squirrel*), the animacy of the possessed (*nut*) and the difference of the lengths of the possessor and the possessed (say, in characters). The two regression equations begin with the dependent variable (Genitive), followed by a tilde meaning 'as a function of,' followed by all included predictors connected with pluses.

(1) Genitive (*of* vs *s*) ~ PossessorAnim + PossessedAnim + LenDiff
(2) Genitive (*of* vs *s*) ~ PossessorAnim + PossessedAnim + LenDiff + PossessorAnim:PossessedAnim + PossessorAnim:LenDiff + PossessedAnim:LenDiff + PossessorAnim:PossessedAnim: LengthDiff

The equation in (1) is multifactorial$_1$: multiple independent variables are studied at the same time. The equation in (2) is multifactorial$_2$: multiple independent variables and their interactions (indicated by the colons) are studied at the same time, which means that the regression in (2), but not the one in (1), can determine whether PossessorAnim has the same effect on the choice of genitive regardless of the level of PossessedAnim, whether PossessorAnim has the same effect on the choice of genitive regardless of what the length differences are, etc. The second type of modeling is statistically much more challenging, but it is often also the more revealing since many studies have shown that independent variables can interact in quite complicated ways. Often, researchers begin with a larger model such as that in (2) and then use various statistical operationalizations of Occam's razor (such as significance tests or information criteria) to trim the larger model down in a process called model selection to a so-called minimal adequate model; the model that, with some simplification, contains all, and only all, predictors that are significantly correlated with the dependent variable.

These regressions are immensely powerful and versatile tools and are now applied to many experimental and observational data sets (but see below). For instance, dependent variables that are reaction times or acceptability judgments would be analyzed with linear regression modeling; binary-dependent variables such as above in (1) and (2) and many other cases of syntactic alternations (such as the dative alternation, particle placement, preposition stranding, analytic vs synthetic comparisons, *will* vs *going to*, etc.) have been studied with binary logistic regressions; and dependent variables with more than two levels have been studied with multinomial regressions in, for instance, the semantic analysis of which of several near synonyms is the most likely choice given a particular context and why.

The above two kinds of models assume that all data points are independent of each other. However, especially in multifactorial settings, this is hardly ever the case: speakers provide more than one response in an experiment, verbs are reacted to by more than one subject, an author provides more than one constructional choice in a corpus file, etc. At the same time, these three variables – Speaker, Verb, and Author – are typically also different from variables such as TimeOfTest (before vs after), SexOfSpeaker (male vs female), or Animacy (animate vs inanimate): The levels of the latter variables (often called *fixed effects*) cover all the possibilities one would expect to exist in the population whereas the levels of the former variables (often called *random effects*) cover only the (ideally random) sample of speakers, verbs, or authors that was included in the study although a researcher would probably want to generalize beyond the set of speakers, verbs, or authors tested.

Dealing with this kind of scenario requires adjustments to the kind of (generalized) linear modeling where independence of data points is required. For quite some time, experimental psycholinguistic studies were heavily influenced by Clark (1973) and Forster and Dickinson (1976), two of the most widely cited early discussion of this problem in psycholinguistics. The current state-of-the-art approach in linguistics, however, involves what is called (generalized linear) *mixed-effects modeling*, or *multilevel modeling*. These models address the dependence by taking into account the variability that is associated with random effects. Consider a scenario in which one dependent variable is modeled as a function of one independent variable on the basis of 10 data points from three speakers each. **Figure 2** represents a regular linear model of some data in the left panel (the numbers 1, 2, and 3 represent the speakers' data points) and it is obvious that a linear model cannot account well for the data. In the right panel, a linear mixed-effects model is computed on the same data where every speaker gets his own intercept but they all share the same slope. In that panel, the dashed line reflects the overall trend and the three straight lines are the separate regression lines for each

Figure 2 A linear model and a linear mixed-effects model (random intercepts) analysis of a fictitious data set.

speaker; the difference between the overall trend and the regression line for speaker 3 is represented by the arrow. Again, it is obvious that this model, which takes the relation between data points of a speaker into consideration, accounts very well for the data.

More complex versions of such mixed-effects model are available, e.g., models where speakers do not just get their own intercepts, but also their own slopes, and these adjustments can be included for crossed and nested variables that have made this a very powerful and popular approach in a very wide variety of experimental and observational studies. While some details are currently still being worked out – how to compute *p*-values for predictors in some models, how to do model selection with mixed effects, how many different random effects to include, etc. – mixed-effects modeling is bound to become one of the most important tools of the trade.

While regression models are probably the most widespread tool for multifactorial statistical analysis, another increasingly popular method is that of *classification and regression trees* or related, but more advanced, methods such as *random forests*. Such trees are based on the idea of successively splitting the data in a binary fashion such that each split groups the data based on one independent variable into two groups that predict the behavior of the dependent variable best. The output of such an analysis is typically a prediction/classification accuracy and a decision tree-like structure and the analyst interprets the tree in a top-down fashion to see which variable splits explain the dependent variable. This method is sometimes used an exploratory precursor to regression modeling, but can also be illuminating in its own right.

Desiderata

The field of linguistics has evolved enormously with regard to the number and sophistication of hypothesis-testing techniques that are now used regularly. However, given the recency of this development, many of the techniques mentioned above need to become more fleshed out in how they are applied to linguistic data and more entrenched among a larger number of practitioners. In addition to these developments, there is also a need for linguists to recognize the multitude of techniques that are already regularly applied in fields that struggle with data that pose the exact same distributional challenges that linguists face every day. Typically, psychology is mentioned as one of the closest neighboring fields whose statistical tools linguists might inspire – however, the field of ecology is maybe an even better contender (cf Zuur et al., 2007, 2009 for examples). This section will briefly outline a few methods that more linguists ought to pay more attention to, given how they can help tackle data and questions that are sometimes hard to address with the currently established tools.

One very basic but still quite useful improvement would involve linguists realizing more the power of regression approaches. For example, if a researcher has done a corpus study and represented his data in a 2×2 frequency table and then wanted to compare these results to another 2×2 frequency table from someone else's previous study, then he might resort to a heterogeneity chi-squared test to see if both data sets may represent the same population. However, not only is this somewhat cumbersome, but the heterogeneity chi-squared test also does not generalize to $r > 2 \times c > 2$ frequency tables. Instead, one natural solution may be to just analyze the data with a regression and test whether the two variables tested for in the chi-squared test also interact with a third variable that indicates which study the data are from. If there is no such significant three-way interaction, then the two data sets can be argued to represent the same population, otherwise, they cannot. Thus, while it may feel like an exaggeration to run a binary logistic regression where a chi-squared test would be entirely appropriate, adopting the regression perspective allows one to pursue a wider range

Figure 3 A linear regression model without polynomial predictors (left panel) and a linear regression model with a predictor as a third-degree polynomial (right panel).

of questions with a single unified modeling approach. (See below for another similar example.)

While conceptualizing some data sets in terms of regressions is already useful, there are of course also extensions and additional methods. Some of these extensions/methods are very closely related to regression approaches. One kind of particularly useful extension allows researchers to handle curvature in data or nonlinear effects. One example would be to include polynomial terms in regression analyses, another more general one is *generalized additive modeling*. Consider **Figure 3** for data on the frequency of the *keep* V-*ing* construction in the TIME corpus (from Hilpert, 2011). While the left panel shows that it is possible to fit a simple linear regression to these data (and even obtain a significant result), the right panel shows that a polynomial to the third degree provides a much better fit with the data and suggests that, after 1995, the growth trend seems to be leveling off.

Another technique linguists may consider using much more is *general linear hypothesis test*. This is a test that can be used as follow-up analysis of a regression model that involves at least one categorical independent variables with three or more levels. Even if such a categorical variable makes a significant contribution to a dependent variable, this does not mean that all its levels need to be maintained. For example, a researcher may distinguish five levels of animacy in his coding of corpus data – e.g., human and deities, animate but not human, plants, concrete objects, abstract entities – and the corresponding variable Animacy might be significant. Then, one can use general linear hypothesis tests to determine whether all five levels of Animacy differ from each other or whether Occam's razor would in fact require to conflate the first two and the next two, which would result in a new version of Animacy with only three levels.

Interestingly enough and as mentioned above, this logic does not only apply to, and would benefit, complex multifactorial regression models – on the contrary: Instead of submitting a, say, 4×2 frequency table to a chi-squared test, one could analyze these data with a Poisson regression and follow up with general linear hypothesis tests to determine whether all four levels of the independent variable are indeed necessary/justified.

Then, there are many statistical tools with huge potential for linguistics. One is *naïve discriminative learning* (NDL) as discussed by Baayen (2010). The overall goal is very similar to that of (generalized) linear mixed-effects modeling but, unlike regression modeling, this algorithm is based on a general model of human probabilistic learning and equations rooted in research on associative learning. As Baayen shows, NDL, while cognitively better grounded than traditional regression models, achieves classification accuracies comparable to other models and can even handle random effects in insightful ways.

Another set of relevant tools includes methods that are designed to address more explicitly the question of causal relations between predictors and responses. Strictly speaking, regression models of the above type only speak to whether there are significant correlations between the predictors on the one hand and the response on the other. However, techniques such as *structural equation modeling* or *Bayesian networks* can help study causal relations better by forcing the researcher to explicitly formulate expectations about how predictors are intercorrelated with each other and correlated with the dependent variable. For example, it is well known that many syntactic/constructional alternations such as the dative alternation or particle placement are correlated with phonological predictors (e.g., stress and syllabic length), syntactic predictors (e.g., definiteness and complexity), and discourse–functional predictors (e.g., givenness/inferrability of referents). However, these predictors are all correlated with each other, which not only poses problems to most regression models but also makes it harder to disentangle cause–effect relations. Applying

the above kinds of tools would require the researcher to hypothesize, for example, that discourse-functional characteristics are causes for phonological and syntactic effects, which in turn are causes for syntactic/constructional choices – rather than treating all predictors as mere causes and only the syntactic/constructional choice as an effect. Since usually causal relations are what we are most interested in, these techniques hold high promise.

Finally, a more general recommendation is that linguists may want to become more familiar with the field of robust statistics (cf Wilcox, 2012). Since linguistic data are rarely well-behaved in the sense of being normally distributed (instead, many phenomena are Zipfian-distributed), not suffering from outliers (many linguistic variables such as lengths and frequencies regularly have outliers), and since grouped data often differ in their dispersion, etc., robust statistics offer ways to analyze data with all these properties that undermine the use of the currently more widespread regular statistical tools.

Figure 4 Results of an HCA of seven nouns on the basis of the frequencies of words they co-occur with.

Hypothesis-Generating Methods

The techniques discussed so far are all usually employed to subject hypotheses to significance testing and decide on which hypothesis to adopt based on a *p*-value. A different set of techniques is concerned with generating hypotheses in the first place. That is, these techniques serve exploratory functions and are often applied to data sets whose size and complexity defies an analyst's eyeballing and pattern-matching skills. Again, this section will begin with a discussion of what are arguably the currently most frequently used methods before turning to some refinements and desiderata that would benefit the field; as before, given that the number of techniques is vast, the overview has to be quite selective.

Exploratory Methods in Common Use

The probably most widespread exploratory technique is *hierarchical cluster analysis* (HCA). As most exploratory methods, this one, too, is typically applied with an eye to determining how n entities – sentences, NPs, words, subjects, etc. – can be grouped into $m < n$ groups/clusters that exhibit high within-group similarity and low similarity to other groups.

HCAs involve several steps: First, one computes how similar each of the n items is to each other item based on a user-defined similarity metric. The results of this step is usually represented in a (dis)similarity matrix. Crucially and unlike other exploratory tools, the items can be compared even if they involve both categorical and numeric characteristics (although numeric characteristics are most frequent). Second, in an iterative process, the pairs of items with the highest similarity values are identified and merged into groups. Once an item enters into a group, it cannot be considered in isolation anymore – what is considered for the next merger is then the newly formed group. In the most frequent type of HCA, this process is repeated until all items have been merged into one group. Third, this grouping process is visualized with a so-called dendrogram and the researcher has to decide how many clusters the dendrogram reflects most revealingly. An example is represented in Figure 4, which is the result of clustering seven nouns on the basis of the frequencies of words they co-occur with in corpus data. Both semantic considerations – the left cluster contains precious-metal nouns, the right one gastronomical terms (although note the ambiguity of *bar*) – and follow-up diagnostics to be mentioned below suggest that assuming the two clusters highlighted with gray boxes is most useful here.

HCA is a very flexible tool, suitable for very many different kinds of both experimental and observational data and often relatively straightforward to interpret, and they are becoming increasingly frequent in linguistic research.

Another frequent technique is *principal component analysis* (PCA, and its 'sibling' principal factor analysis). The overall goal of a PCA is quite similar to that of an HCA, but the underlying mathematics are quite different and PCA is only applied to all-numeric data. The input data is the same as for an HCA and a PCA proceeds by computing all possible intercorrelations between the n items/columns being studied. Then, the PCA merges/compresses the n items/columns into $m < n$ principal components, such that the items/columns within a principal components are highly intercorrelated but all principal components are usually mutually orthogonal, or independent of each other. This can mean, for example, that a PCA would convert a data set in which NPs are classified according to $n = 20$ characteristics into a new data set where, say, only four principal components retain more than 90% of the information of the originally 20 columns. This kind of result is why PCA and other similar methods – for example, *multidimensional scaling* or *correspondence analysis* – are also referred to as dimension-reduction methods. A researcher can then 'just' analyze the nature of the principal components – what are the linguistic characteristics that make up the principal components and why? – and often this interpretive task is facilitated by a two-dimensional visual representation of the results, as exemplified in Figure 5, where the seven nouns are grouped in a way that resembles the above results of the HCA.

Figure 5 Results of a PCA of seven nouns on the basis of the frequencies of words they co-occur with.

Alternatively, the compressed data set can also be used as input to hypothesis-testing methods, which are now more likely to return useful results, given that instead of 20 intercorrelated variables, now only 4 uncorrelated variables, the principal components, are studied. In corpus linguistics, factor analyses have been extremely influential in, for example, Biber's (1995) work on register/genre variation, but many studies in computational semantics employ mathematically very similar methods.

Desiderata

Just as above, the desiderata regarding exploratory methods come in two kinds: First, as extensions of, or follow-ups to, the methods discussed above; second, methods in addition to the ones discussed above.

As for the former, while cluster analyses enjoy quite some use now, the results they provide are often not yet analyzed to their fullest extent. For instance, not all dendrograms are easy to interpret in terms of how many clusters a researcher should assume but very few studies discuss principled ways of arriving at such decisions. One approach to this question involves a statistic called average silhouette widths, which quantifies how similar elements are to the clusters which they are in relative to how similar they are to other clusters; in the above case of **Figure 4**, this statistic 'recommends' to assume the highlighted two clusters. Another approach toward the same problem involves resampling approaches that, ultimately, assign a *p*-value to each possible cluster so that researchers can pick the most strongly supported and most robust clusters for interpretation. In spite of the availability of such methods, they are still too rare, which can render HCA results less insightful than they would need to be. Finally, one rarely sees decisions for a particular number of clusters validated by some other statistical technique. For instance, if a cluster analysis really reveals two clusters, then a binary logistic regression (or some other non-clustering technique) should also be able to recognize these two clusters in the data – attempts at validation like these are still hard to find.

A different set of extensions involves the interpretation of the clusters: what in the data is most responsible for a particular cluster; what gives rise to the structures; which variables are reflected most in the clustering? There are diagnostic statistics available to answer such questions, but they have not yet made their way into the relevant research literature.

As for the latter kind of desiderata, there are several relatively new methods that should be highly useful to linguistic research. One of these is actually another cluster algorithm, but one with underutilized properties. This approach, so-called *fuzzy clustering*, allows for items to be members of more than one cluster and to different degrees, which is often a much more realistic assumption than the seemingly clear-cut divisions of items into clusters suggested by traditional dendrograms. Another technique that might be very useful is that of *association rules*, a data mining procedure suitable to uncover co-occurrence and *if … then* relations. The most attractive features of association rules are their conceptual simplicity and that this method can handle extremely large data sets (think Amazon shopping-basket data) consisting of categorical variables, which are not amenable to multiple cross-tabulation anymore. Thus, especially large-scale corpus data might benefit from this method.

Concluding Remarks

It is useful to conclude by mentioning a few, more general desiderata which, if they were more widely implemented or adhered to, would also tremendously help the discipline of linguistics evolve. The first of these is concerned with the fact that we not only need to broaden and deepen our knowledge of statistical methods per se, but we also need more awareness of the distributional assumptions that many methods come with. Many published studies are quite cavalier when it comes to these, but, as discussed at length in the above-mentioned Wilcox (2012) study, failure to deal with violations of such assumptions can lead to hugely anticonservative results.

In addition, the field also needs more and firmer guidelines on what is important in statistical analysis, what is important to report (e.g., checking distributional assumptions), and how methods and results should be reported. Other fields have had long and intense discussions about these issues whereas linguistics, for the most part, has not. We should be prepared to be inspired by how other disciplines with similar kinds of questions and data have come to grips with these challenges and recommendations such as Wilkinson and the Task Force on Statistical Inference (1999) provide many essential tips (e.g., to always include effect sizes to distinguish significance from effect size and make analyses comparable).

Finally, two areas in statistics that linguists should strive to learn about more: (1) developments in *resampling approaches* such as bootstrapping, which can be quite useful to enhance the precision and generalizability of our results; (2) *Bayesian statistics*, which adopts a perspective on statistical analysis that is very different from the predominant null-hypothesis significance testing approach, but which is ultimately more

in line with what we as researchers are interested in: the confirmation of reasonable hypotheses and the quantification of effects on the basis of accumulated knowledge. Given the diversity and complexity of linguistic data, any kind of tool can only be a welcome addition to our toolbox.

Quantitative Methods and Crime

Abstract

Crime emerged as a topic of quantitative study in the eighteenth century and scholars today analyze it using methods drawn from all of the social sciences. Crimes are distinctive for their rarity and for their social and geographic concentration. One response to these features is to adjust for them when performing standard statistical analyses. An alternative is to take the features as essential aspects of the phenomenon under study, and give them an important role within models for longitudinal and spatial data.

Crime has been a subject of quantitative investigation for more than 200 years, and sophisticated analyses became common well before criminology emerged as a self-conscious area of inquiry. Crime and related phenomena are serious concerns in large-scale urban societies, and they generate a relative wealth of formal records. Due to their availability and inherent interest, these records are then natural objects of study.

History of Quantitative Crime Analysis

Criminal trial verdicts were a topic of much discussion in eighteenth- and nineteenth-century France, and important statistical ideas resulted from analyses of jury decision-making behavior (Hacking, 1990). Early work on conviction probabilities by Condorcet and Laplace was entirely of a mathematical character and did not consider the results of actual court cases. Research on trials adopted an increasingly empirical focus, however, as the collection of criminal justice statistics became routine. Among the prominent contributors to this literature was Poisson, who developed his probability distribution for rare events and his law of large numbers in studying trial data (Stigler, 1986).

Expansion in the number and variety of state-recorded social statistics also encouraged research on the incidence and correlates of crime. Both Quetelet and Guerry used data on crime rates to undertake tests of causal hypotheses, and crime came to join suicide as a staple topic of statistical analysis (Hacking, 1990). In the succeeding years, studies of crime data have been at least a minor interest in all of the social sciences, as well as in public health and related fields. As analytical procedures developed in these areas, scholars applied them to questions involving criminal offending and victimization.

Today most major analytical methods see use in criminology, and researchers are quick to adopt new approaches when they appear. Criminology is an interdisciplinary area of study, and it maintains few fixed ideas about proper research designs or analysis techniques. As a result, the field is receptive to innovative strategies of all types. The articles in Piquero and Weisburd's (2010) edited volume provide examples of the wide scope of quantitative criminology during the early twenty-first century.

Sources of Quantitative Crime Data

Most quantitative studies of crime and criminal justice issues rely on the analysis of observational data. Experiments and quasi-experiments also appear with some frequency in the empirical literature, and criminologists hold the rigor of these research designs in high esteem. Practical and ethical considerations nevertheless limit the situations in which experimental control is feasible, and researchers must usually instead take their data as they naturally occur.

Quantitative information on crime is available in diverse forms, varying in purposes and methods of collection. Although the accuracy of these numbers is always open to some degree of doubt, they are often publicly available or otherwise easy to obtain. Most analyses of crime use data from one of three general sources.

First, police agencies collect reports of the crime incidents that come to their attention. In the United States, the Federal Bureau of Investigation (FBI) has since the 1930s compiled counts of crimes and arrests through the Uniform Crime Reporting (UCR) program (Barnett-Ryan, 2007). The UCR data cover a range of serious offenses at the city, state, and national levels, and they support aggregate time series and cross-sectional studies. Local police agencies often provide additional information about criminal incidents, including their locations and characteristics. The FBI's National Incident-Based Reporting System offers a similar level of detail, but police agencies have been slow to embrace it. Other nations also maintain publicly available crime statistics, although differences in legal definitions and questions about accuracy limit their uses in international comparisons (Newman, 1999).

Surveys of victims are a second major data source. A victimization survey draws a sample, determines if the respondents were crime victims, and gathers information about both the victims and crimes. The National Crime Victimization Survey (NCVS) in the United States is an example of this approach (see Rennison and Rand, 2007, for a description of NCVS methods). Surveys like the NCVS allow study of crime outcomes for individuals or large aggregates. They do not have as fine a level of geographic resolution as do police-recorded crime counts, but they give more detailed data on individual incidents. Many nations sponsor their own victimization surveys, and the International Crime Victimization Survey

collects data from multiple areas of the world using a standard format (Van Dijk et al., 2008).

The third source of data comes from surveys of offenders, most often from adolescent populations. The surveys ask respondents to self-report their participation in criminal activities, permitting comparisons of the offenders with their law-abiding peers. Unlike the other two data sources, no government agency sponsors a long-term self-report survey. Numerous private surveys exist, however, and data from these studies are often freely accessible to the broader research community.

Besides data about crime, extensive amounts of quantitative information also exist on associated phenomena. These include data on prisons and jails, law enforcement agencies, and criminal courts. The statistics about the criminal justice system are helpful in understanding crime, and they involve significant areas of study themselves. Within the United States, the federal Bureau of Justice Statistics compiles and distributes several large-scale data series on these crime-related topics (Groves and Cork, 2009).

Analysis of Quantitative Crime Data

Quantitative criminology has yet to develop a distinctive set of analytical techniques, and researchers instead use methods that originally appeared in other fields. As in most areas of the social sciences, studies in criminology rely heavily on the linear regression model and its many variations.

Two features of crime data nevertheless have implications for empirical analysis. First, crime is a rare event, and most members of a population manage to avoid it as either offenders or victims. In the United States as a whole, for example, only one person in 20 000 was a murder victim during 2010 (UCR data). Considering more common offenses, less than 1 US household in 40 suffered a burglary during that year, and less than 1 in 200 reported a motor vehicle theft (NCVS data).

Second, the frequency of crime varies greatly across social units and physical locations. A relative handful of offenders commits a disproportionately large share of serious criminal acts, and the burden of crime falls heavily on a similarly small group of victims. Offending is also concentrated within group settings, so that delinquents more often commit crimes when they are in the company of others (Thornberry et al., 2003). Besides these social concentrations, criminal incidents cluster in space, with many crimes occurring in a small set of geographical places.

Among the large body of research documenting the unequal distribution of crime across individuals, a study by Wolfgang et al. (1972) was particularly influential for later work. Wolfgang and colleagues followed a birth cohort over time, and they found that about 6% of the cohort's members accounted for 52% of its total arrests. The spatial concentration of crime also has a high level of empirical support. A prominent study by Sherman et al. (1989), for example, found that 3% of Minneapolis street addresses generated 50% of all calls for police services in the city.

The rarity and concentration of crime in turn imply that the frequency of criminal incidents will have a highly skewed distribution, especially in small samples. Most of the cases will be at the distribution's low end, and a long right tail will extend off toward the higher counts. Due to the social and spatial clustering, criminal incidents will also be correlated with each other over time and space.

Skewed and correlated data pose problems for conventional regression-based analysis methods, which usually assume independent Gaussian observations. Application of transformations to induce normality can often reduce or eliminate the long tails in distributions of offenses and victimizations. Appropriately weighting the observations or substituting distributions like the negative binomial for the Gaussian can similarly allow for both skews and lack of independence (see, for example, Osgood, 2000). In practice, these adaptations give researchers the ability to conduct analyses using extensions of the conventional models for regression and other popular methods.

Longitudinal and Spatial Analysis of Quantitative Crime Data

Although quantitative studies of crime can in most cases successfully apply modifications of standard techniques, the unique features of the data make some types of methods especially attractive. The clustering of criminal incidents creates problems for conventional practice, but it also opens analytical possibilities. In particular, methods for studying within-unit changes and spatial dependencies exploit the information that clustering provides, and crime researchers often apply them.

Longitudinal analyses take advantage of the concentration of offending within units to examine how criminal activity varies over time. Longitudinal studies observe a sample of units in two or more time periods and use the repeated measurements to compute individual levels of change. One class of methods accomplishes this goal by using fixed or random effect analytical models. Longitudinal studies often focus on juveniles, and the interest is in how involvement in crime evolves over the life course. By linking the past and future, these models also allow study of dynamic temporal patterns of change (see, for example, Horney et al., 1995).

Extensions of longitudinal methods consider the shape of the time path connecting earlier and later periods. The simplest extensions use polynomials in time to model nonlinear developmental sequences. More elaborate variations include growth curves that differ across individuals depending on the values of other variables. The growth curve models generally involve the use of methods for the analysis of multilevel data (Singer and Willett, 2003; Bryk and Raudenbush, 2002).

A technically different but conceptually related approach addresses the possibility of distinctive growth trajectories among population subgroups (Nagin and Land, 1993). Although several classes of trajectory models are available (Kreuter and Muthén, 2008; Nagin, 2005), all have the goal of identifying latent classes of cases that follow a common time path. Trajectory models consider if a set of clearly defined developmental patterns exists within a population, and they allow study of how these patterns differ depending on the values of other variables.

Collectively, longitudinal methods attempt to take advantage of the information that within-unit clustering provides.

Spatial methods have a similar goal, but here the clustering is cross-sectional, over geographical units at a single time point. Also, while the units in longitudinal studies are often individuals, spatial analysis units are almost always collective aggregates, such as neighborhoods or other large areas.

In elementary applications, spatial analyses plot the locations of criminal incidents on maps and use these visual displays to make inferences about the distribution of offending. This type of analysis has blossomed with the availability of capable computing equipment and the development of geographical information system (GIS) software.

Police departments increasingly attach street addresses or global positioning system data to crime incident reports, allowing the creation of detailed and question-specific displays (Parker and Asencio, 2008). The New York City Police Department was an early leader in applying GIS technology to identify crime concentrations, or 'hot spots.' By some accounts, increasing police activity in hot spot areas helped produce the dramatic crime reductions that the city began to experience in the 1990s (Batton, 1998).

Beyond mapping, statistical analyses of spatial crime data take several forms. One approach is to estimate a regression model that adjusts the results for spatial dependence in the error term. This type of analysis gives no explicit attention to the geographical characteristics of the data, and instead regards them as nuisance features that complicate an analysis. An alternative is to allow the spatial structure of the data to affect crime outcomes directly through mechanisms of contagion and diffusion. Identifying clusters of criminal offenses and their boundaries is also a common application of spatial methods, and is a natural accompaniment to mapping (Parker and Asencio, 2008). In these cases, the geographic distribution of crimes is a central element of the analysis.

Future Directions

Quantitative study of crime is now almost entirely a matter of data analysis, and most researchers devote their efforts to estimating population characteristics and relationships between variables. Existing work correspondingly gives little attention to developing a mathematical understanding of the processes that underlie crime and criminal justice outcomes. Despite its current neglect, formal mathematical modeling is a potentially important avenue for future research in the area. Such an effort could contribute to an explanation of crime clustering, for example, rather than simply taking the concentrations as a given. Adopting a more theoretical focus would coincidentally also move quantitative investigation of crime back toward some of the intellectual approaches from which it began.

Quasi- and Field Experiment

Abstract

Field trials and quasi-experiments are comparative tests in which we assess the effects of one intervention (or a set thereof) on a group of subjects as compared to another intervention on another group of similar characteristics. The main difference between field trials and quasi-experiments is in the way the interventions are assigned to the groups: in the former the allocation is randomized whereas in the latter it is not. We are going to see first the different roles played by randomization in medical experiments. Then we will discuss how controlled field trials, originating in psychology, spread to the social sciences throughout the twentieth century. Finally, we will show how the idea of a quasi-experiment appeared around a debate on what constitutes a valid test and what sort of controls guarantee it.

Field Experiments and Quasi-Experiments

Field experiments and quasi-experiments are comparative tests in which we assess the effects of an intervention (or a set thereof) on a group of subjects as compared to another intervention on another group of similar characteristics. The main difference between field trials and quasi-experiments is in the way the interventions are assigned to the groups: in the former the allocation is randomized whereas in the latter it is not. For more than a century now, there is an ongoing debate about what sort of methodological controls in the comparison warrant causal inferences in such experiments. In particular, it is under discussion in what sense randomized allocations provide superior grounds for causal inferences. We are going to see, in the first place, the roles played by randomization in medical experiments. Then we will discuss how controlled field experiments, originating in psychology, spread in the social sciences throughout the twentieth century. Finally, we will show how the idea of a quasi-experiment appeared around a debate on what constitutes a valid test and what sort of controls guarantee it.

Randomized Experiments

Randomized experiments originate mainly in medicine, where the fair comparison of therapies is well documented centuries ago. As early as in 1662, the Flemish physician J.B. Van Helmont suggested settling a dispute about the efficacy of bloodletting and purging with a randomized allocation of treatments: "Let us take out of the hospitals […] 200 or 500 poor people, that have fevers, pleurisies. Let us divide them into halves, let us cast lots, that one halfe of them may fall to my share, and the other to yours; I will cure them without bloodletting and sensible evacuation; but you do, as ye know […]. We shall see how many funerals both of us shall have." A 1747 test of six remedies for scurvy is considered the first actually controlled trial: conducted by James Lind, a naval surgeon, it showed the superior efficacy of (vitamin-C-containing) oranges and lemons as compared to the other alternatives (against the opinion of both the Royal College of Physicians and the Admiralty). As Iain Chalmers (2006) has extensively argued, randomization originated in comparative experiments as a method for the correction of biases in the allocation of the tested treatments. If randomized, the preferences of the experimenter allocating them would not contaminate the comparison (e.g., assigning her favorite treatment to one particular group of patients). Randomization was just one possible *control* for the selection bias; an alternative one was alternating treatments between patients. Medical experimenters identified many other biases in their tests, developing *controls* for them (e.g., blinding as early as 1784). As it often happens with error-correction procedures in most scientific fields, these debiasing methods were grounded in the experimenters' experience, without any substantial theory to account for their efficacy. In the first decades of the twentieth century, medical trials implementing all sorts of controls were common, but the standardization of the randomized clinical trial (RCT) began only with the 1947 test of Streptomycin, an antibiotic drug, commissioned to Austin Bradford Hill, a medical statistician, by the British Medical Research Council (Teira, 2013a).

Hill relied on the foundations for experimental design developed by the great statistician Ronald Fisher for agricultural research on fertilizers and soils. Fisher used randomization (now explicitly defined on the probability of receiving a given treatment) to ground significance testing: how likely it is to observe an experimental outcome equally or more extreme than the one actually obtained in an infinite series of repetitions of the trial? Randomization secured that the actual allocation of treatments was just one random draw in that series so we could calculate the *p*-value for the actual outcome obtained on the basis of the distribution of all outcomes for every possible allocation. Furthermore, Fisher defended the role of randomization in causal inference: The interference of potential confounding factors could be disconnected from the treatment outcome in a series of replications of the experiment if the allocation was randomized.

Bradford Hill merged these three roles of randomization (debiasing, significance testing, causal inference) in the trial of Streptomycin, establishing the first template for the RCT. The pharmaceutical revolution of the 1950s also brought about the expansion of drug testing, and the template was gradually refined with further debiasing controls (e.g., double blinding) and statistical tools (e.g., power calculations, showing the

adequate sample size for a statistically sound test). In 1962, RCTs for safety and efficacy became compulsory for the regulatory approval of new drugs by the US Food and Drug Administration. This created a booming industry of pharmaceutical trials still alive today, although under serious discussion (Goldacre, 2012).

Field Experiments in the Social Sciences

The history of field experiments in the social sciences is still to be written. The few existing accounts have not so far been inclusive of all the social scientific disciplines, and this leaves us with a fragmented portrayal of experimentation in the social science. In the case of economics, for instance, and according to Steven Levitt and John List (2009), the use of field experiments originated in the early twentieth century, growing gradually to an upsurge in the last decade (the 2000s). Here we will motivate the importance of two questions that arise in the light of this yet fragmentary history: How did social scientists reach a consensus on the experimental design of field trials? Why did they use this design so scarcely until recently? The methodological design and interpretation of a field trial is in itself far from obvious: In principle, we are trying to grasp the causal effect of an intervention comparing it with an alternative one on two groups of subjects, both entirely alike except for the effect of the intervention. We find explicit methodological discussions on such comparisons in the nineteenth century (e.g., Mill's method of difference), but experimenters need to agree, on the one hand, on the controls they impose on the two groups in order to make sure that no confounding factors make a difference between them. And, on the other hand, if there is a quantitative difference between the outcomes, experimenters need to agree also on a statistical procedure to assess the effects.

Historians of statistics, following Theodore Porter (1995), have shown how the use of statistical techniques in public policy was presented as an alternative to expert judgment. RCTs in medicine came to replace the opinion of individual doctors about the efficacy of treatments (sometimes based on laboratory evidence, often just on their own clinical experience). Of course, many physicians considered their judgment objective enough to ground the assessment. And, furthermore, a comparative approach was often considered unethical since it would deprive a group of patients of a treatment that a physician would have recommended otherwise. This is why the agreement on a comparison constrained by a series of controls (often on the physician administering the treatment) was only reached after several decades in the 1970s, when the first meta-analyses started ranking trials for the aggregation of evidence (for an instance of such lists of controls, see Bero and Rennie, 1996).

As to the assessment of the comparison, right from the beginning there were serious divergences on what were the proper statistical grounds to judge the difference between interventions (Teira, 2011). The controversy between Fisher and Jerzy Neyman in the 1930s is well documented; for instance, both parties shared a frequentist conception of probability, but disagreed on how to apply it to an experimental test of a given hypothesis. Fisher wanted to rely exclusively on *p*-values: Assuming the truth of the hypothesis that there is no difference between treatments, if we observe a substantive divergence between the two groups, either an exceptionally rare chance has occurred or the hypothesis is not true. But the data alone cannot establish whether the former or the latter is the case (or whether both are). Neyman, together with Egon Pearson, developed a different rationale for the testing of hypotheses: Instead of assessing the plausibility of a single (null) hypothesis, we should have a criterion for choosing between alternative exclusive hypotheses, with a known probability of making the wrong choice in the long run. Fisher considered this latter approach suitable only for industrial quality controls, but epistemically ungrounded. Neyman opened the way instead to a decision-theoretic appraisal of hypothesis testing. Eventually, it led to a full-fledged Bayesian alternative, already emerging in the 1960s and thriving today, in which RCTs can be designed and interpreted without neither randomization nor *p*-values.

Hence, the history of field trials cannot be written, as Leavitt and List suggest, as if once Fisher statistically grounded the design (randomization plus significance testing), it just spread to the medical and socials sciences without controversy. For instance, Stephen Ziliak (2014) shows that even randomization was controversial in proto-economic trials: Already in the 1910s, the pioneer of statistics, *Student* (the pen name of William Gosset) defended a balanced design of agricultural plots as an alternative to randomization, since the confounding factors are not independent and identically distributed.

Historically, field trials emerged among many other approaches to social observation (see, e.g., Maas and Morgan, 2012 regarding economics) and the different controls in their experimental design were tried one by one in a variety of settings. According to Stephen Stigler (1992) and Ian Hacking (1988), the philosopher Charles S. Peirce, together with his student Joseph Jastrow, conducted the first sound randomized experiment in psychology between 1883 and 1884. It tested Fechner's hypothesis about the existence of a perception threshold below which one cannot discern small differences. The experimenter presented different weights to the subject, ordering them according to the cards drawn from a standard deck. Peirce used this randomization scheme as a debiasing procedure (in order to control the subject's guesses about weights), without any explicit statistical implication. Yet the procedure was not adopted in subsequent experiments on the topic, although it was actively used in all sorts of experiments on telepathy for several decades.

According to Trudy Dehue (1997), by the end of the nineteenth century, out of Fechner's psychophysics research program emerged a causal approach to the study of learning transfer (subjects were asked to perform an ability task with either the left or the right hand to measure gradual performance improvement and then they were tested to see whether the trained skill had transferred to their other hand). This causal approach, of which randomization of treatments was already an integral part, was gradually adopted by psychologists of education, led by the Columbia psychologist Edward L. Thorndike, and eventually came to be increasingly implemented at a major scale in American educational research. Here, still according to Dehue, the Stanford psychologist John Edgard Coover presented the control group in 1907 as a methodological device to correct

a confounder in training experiments: Anyone who takes the same test twice is likely to do better the second time – on top of the multiple factors that may affect the subject in between. In the 1910s, control groups were used in experimental educational research conducted in schools on the most effective means to teach. In the 1920s, we found a variety of comparative studies with different controls (Oakley, 2000, pp. 164–168) and different degrees of quantitative analysis. For instance, after graduating with Thorndike in Columbia, William McCall (1923) started testing the validity of classroom practices with control groups, using randomization as an allocation procedure.

The 1920s were the age of quantitative research in American social science (Porter and Ross, 2003; Oakley, 2000, pp. 163–197). Although educational research was gradually left behind, psychology became a science of controlled experiments, with controls intending to warrant bias-free causal analysis, favoring the laboratory to the field. This is how it features in the methodological handbook of the Social Sciences Research Council (SSRC, 1932), a major funding body of American social science at that point. Statistics, and in particular statistical economics, dealt instead with experimentally uncontrolled factors. Nonetheless, other social scientists tried to do controlled field research: still in Chicago and under the influence of Charles Merriam, the political scientist Harold Gosnell (1927) tried to find a third way studying the factors influencing voter turnout on 6000 Chicago citizens. Gosnell divided them into an experimental and a control group organized by place of residence; the former received notices urging them to register and vote, and their turnout was followed up in elections in 1924 and 1925.

The statistical techniques implemented in these early field experiments (often Pearson's correlation theory) did not contribute much to differentiate between true and spurious causes (Turner, 2007). The weight of causal inference still lied on the controls, where randomization was not always the most prominent. For example, another Columbia graduate, the sociologist Francis Stuart Chapin (1947), introduced the term *ex post facto experiment* to name studies where the conditions are not manipulated but selected by the investigator and the comparison is controlled by matching groups – considered a licit alternative to randomization.

Fisher's statistical foundations were explicitly incorporated into the design of these trials already in the 1940s (e.g., Lindquist, 1940). Yet, in fields such as educational research this approach apparently did not yield significant results stimulating further research (Oakley, 2000). However, field trials in the social sciences did not take off until the 1960s (Dehue, 2001). Just as it happened with RCTs in medicine, its success owes much to American regulatory pressure: Several Acts enacted by Congress in the early 1960s mandated evaluation of the programs implemented, just as the 1962 Food and Drug Administration required 'adequate and well-controlled clinical studies' for proof of efficacy and safety of new treatments. However, whereas in the three following decades thousands of RCTs would be conducted, in the social sciences there were only a few hundreds. A paradigmatic field trial of this "golden age of evaluation" (Oakley, 2000) is the New Jersey Income Maintenance Experiment (NJIME), conducted from 1968 to 1972, with nearly 1500 participant households at a cost of $7.8 million (1971). Based on the doctoral dissertation of Heather Ross (1970), the trial tested a welfare policy suggested by the economist Milton Friedman: a negative income tax, by which people earning below a certain amount would receive supplemental pay from the government instead of paying taxes to the government. The general intuition is that, unlike indirect assistance schemes, this negative tax would give people incentives to work and sustain themselves. The NJIME tested whether different combinations of income guarantees plus a tax rate on other income had an effect on the work effort of the participants or prompted any other lifestyle changes. This was all followed by questionnaires every 3 months. The initial assessment of the outcome concluded that work effort did not decline in the treatment group (measured by the number of hours of employment), although further analyses of the data pointed out that there was indeed a reduction. The negative income tax worked better in this respect than some welfare schemes though, but it did not outperform others. The NJIME had a control group and treatment allocation was randomized, but a number of potential confounders and biases were soon detected (Greenberg and Shroder, 2004, pp. 194–195): for example, misreporting of earnings or misrepresentation of the sources of income of families. Many other trials dealt with a variety of policies and social settings, with different degrees of success – for a review see Oakley (2000), pp. 198–230; Greenberg and Shroder (2004).

During this golden age of trials in the 1960s and 1970s, a new discipline, *evaluation research*, gradually emerged. In close collaboration with administration researchers, truly interdisciplinary groups of social scientists coming from different disciplines, such as economists, sociologists, educational researchers, and psychologists, participated in evaluating the different aspects of implemented policies and programs, making widespread use of both experimental and nonexperimental methods (Alkin, 2012). Central to this team of new policy evaluators was Donald T. Campbell, a Berkeley graduate in psychology, with broad interests in the social sciences, philosophy, and the methodology of causal inference. The publication of Campbell and Stanley's book in 1963 (republished in 1966 under a more general heading) was a major breakthrough in methodological research for the social sciences (experimental and else), and it still is among the most widely cited social scientific methodological works. As we will see, Campbell and his collaborators helped to create a unified language for policy evaluators in their analysis of both experimental and nonexperimental data and their work was instrumental in the listing and systematization of the possible biases that can threaten experiments, some of which are specific to experimentation in the social sciences.

From a statistical standpoint, field trials reached maturity, integrating full-fledge hypothesis testing and power calculations – although the controversy on its proper interpretation has not completely vanished: it is still open to discussion under which circumstances statistical significance provides good enough grounds to interpret the test of hypotheses (e.g., Ziliak and McCloskey, 2008).

The experience accumulated in this golden age showed a number of biases that might interfere in the outcome of the experiment. Levitt and List (2009) list, for instance, the following: *randomization bias*, by which the allocation process

would exclude risk averse participants; *attrition bias*, participants drop out of the experiment more in one of the groups, biasing the comparison; the *Hawthorne effect*, participants change their behavior because they know they are being observed in an experiment; *substitution bias*, by which the participants in the control group violate the protocol seeking alternatives to the treatment they receive. The problem with these biases is that there might not be an obviously effective debiasing procedure (e.g., Teira, 2013b). In other words, the list of controls that would bring about a consensus on the outcome of trial is still under discussion.

In recent years, a third generation of field trialists has emerged with great strength in economics. Led by the Abdul Latif Jameel Poverty Action Lab (J-PAL) at the MIT, a cohort of development economists are testing social interventions in third world countries, where the costs of implementing such programs are significantly lower. The randomization of treatment often takes place in naturally occurring settings, and the participants often remain unaware of the experiment conducted (correcting thus the randomization bias and the Hawthorne effect). Trials are often designed for theoretical purposes (theory testing or parameter measurement), but their current popularity owes much to their promise of delivering evidence-based policies to fight poverty. In this respect, trialists such as Esther Duflo (2010) advocate the necessity of an evidence hierarchy for policy making: such as physicians use evidence-based rankings to decide on prescriptions according to the best available data (with meta-analyses and RCTs on top of the pyramid), social scientists should ground their recommendations according to the same principles. Are field trials as reliable regarding policies as RCTs with drugs? The future of the field will probably depend on the answer social trialists deliver in the forthcoming years (Teira and Reiss, 2013).

Quasi-Experiments

Although an enthusiast and public advocate of social experimentation, Campbell was well aware of the fact that randomization was often not feasible in the social realm (due to ethical, administrative, or pragmatic obstacles). With this in mind, Campbell developed the idea of quasi-experiments and developed a system of different designs that fell under the category (Campbell and Stanley, 1963). Although the term quasi-experiment had previously been used by other authors, Campbell fixed and systematized its use to the current one. Quasi-experiments share with all other experiments a similar purpose (to test descriptive causal hypotheses about manipulable causes) as well as many structural details, such as control groups and pretest measures. But, by definition, quasi-experiments lack random assignment of groups to treatments. Assignment to the different interventions can occur either by means of participants self-selection or, alternatively, by means of administrator selection, by which teachers, bureaucrats, or researchers decide who gets what treatment. In the latter case, quasi-experimenters may still have a considerable control over how the assignment is executed.

What gives quasi-experiments their close-to-experimental nature is that the cause is manipulable and occurs before the effect is measured. However, since the allocation to conditions is not performed at random, the inferences that can be made from results are typically limited, because we cannot rule out the existence of systematic differences between groups originating in a confounding factor. These differences will often constitute alternative explanations for the observed effect, in direct competition with the tested treatment. Researchers, though, may explore these alternative explanations and rule some or even all of them through other alternative tests either *ex ante* or *ex post*. However, in cases in which this potential list of alternative explanations is very long, quasi-experimental results may not be conclusive. Quasi-experimental designs need to be very carefully planned in order to minimize the potential threats that stem from the lack of randomization. For this reason, quasi-experiments tend to be more complex than true experiments both in their design and in their analysis (Shadish et al., 2001).

One of the most important outputs of Campbell's methodology is his approach to the question of experimental validity, an approach he transposed from previous concepts of measurement validity in psychology into social scientific experimentation (Heukelom, 2011). Campbell first introduced the terms in his 1957 article "Factors Relevant to the Validity of Experiments in Social Settings." In this first definitional attempt, internal validity was seen as the basic minimum requirement of an experiment, expressed by reference to the following question: "did in fact the experimental stimulus make some significant difference in this specific instance?"; and external validity, in turn, referred to the question of representativeness, or generalizability: "to what populations, settings, and variables can this effect be generalized?"(1957, p. 297). Though certain aspects of Campbell's validity typology have been controversial since the beginning, the distinction between internal and external validity remains a central tenet of the contemporary conceptual assessment of experimental validity (Jiménez-Buedo and Miller, 2010).

After this initial definition, Campbell, together with a number of collaborators gradually reformulated the distinction between internal and external validity and gradually added more validity types into what is now a stable fourfold validity typology: *statistical conclusion validity*, *internal validity*, *construct validity*, and *external validity*. Statistical conclusion validity has been defined as the validity of inferences about the correlation between treatment and outcome. Construct validity refers to the inferences about the higher order constructs that represent sampling particulars (Shadish et al., 2001). These latter two concepts, though common currency in social psychology and related fields in the social sciences, are much less used in more recent experimental fields, like behavioral economics. Often, the first two concepts (statistical conclusion and internal validity) are usually grouped together, whereas construct and external validity are also often conflated, suggesting, in accordance to Campbell himself (Shadish et al., 2001), that all of the categories can be subsumed under a broader, more encompassing, internal/external pair.

Campbell developed this methodological discussion as a reaction against an unreflective use of randomization in social psychology, as if it were the only necessary control to secure the validity of an experiment. Through the years, the validity typology helped to identify and analyze a series of

common sources of biases, or threats to validity. Examples of threats to internal validity are phenomena like *selection* (of units to treatments), *history* (i.e., the existence of concomitant events to the treatment that may be actually responsible for the observed effect), *differential attrition* (or mortality) of subjects in the different experimental groups, or *maturation*, where naturally occurring changes over time could be confused with a treatment effect. All of these are confounding factors that can be mistaken for effects of the implemented treatment. In turn, threats to external validity usually originate in confounders that may lead us to infer erroneously that a causal relation will hold over contexts other than the one under study. Examples of such threats are the interaction of selection and treatment (where the relation between x and y will not hold beyond the type of subject who took part in the experiment), or interaction of setting and treatment (where the relationship between x and y will only hold in the experimental setting). Knowledge about these 'threats' was, for Campbell and his collaborators, a matter of practice: detecting ways in which experimentalists were arriving at wrong inferences from looking at the results of their experiments was thus for Campbell a collective, inductive process and very importantly, relative to the details of a particular study. Therefore, the lists of validity threats never intended to be exhaustive, and many additions (and subtractions, and reclassifications) were made over the years.

The list of threats is still to date routinely used for those purposes by field social experimentalists that contrast it, when choosing experimental designs, with feasibility or budgetary constraints. Campbell though was always careful to remind us that performing these checks did not safeguard any design from a potentially infinite list of threats. In this sense, Campbell showed some concern and went as far as considering the lists potentially 'dangerous if they led readers' to overestimate their capacity as shields from error (1986, p. 154). This overestimation, for its practical implications, seemed a bigger concern to Campbell than the fact, of which he was also aware, that his distinction between internal and external validity had been often misunderstood in ways that portrayed it as having to do with the distinction between field experiments and pure laboratory research (Jiménez-Buedo, 2011).

As regards the choice between lab versus field experiments, there has been, historically, a vivid debate concerning the advantages of both in social psychology. Among the early supporters of field experiments, we find Kurt Lewin (e.g., 1939), who highlighted the need to focus on the balance of forces influencing behavior in social situations, developing methods to perform experiments in everyday life scenarios. During the twentieth century, psychology mostly focused on controlled laboratory experiments, but in the 1960s, authors like McGuire (1969) vindicated again field experiments in social psychology from a methodological standpoint.

The enthusiasm for the field and immersive experimental settings in the 1960s also yielded Stanley Milgram's and Philip Zimbardo's famous experiments on obedience and interpersonal dynamics. Milgram (1963) reproduced a clinical scenario to observe obedience to authority: Participants were instructed to administer electrical shocks to other participants and witnessed the (pretended) consequences of pain and disgust. Zimbardo and colleagues reproduced the structure of a prison in the basement of a Stanford building and instructed participants to behave like wards and prisoners, which resulted in a hostile atmosphere as participants followed the instructed roles (see, e.g., Haney et al., 1973). Such extreme social interactions somehow dissuaded other psychologists from following this experimental path and, as of today, social psychology still hinges more on the laboratory than on the field (Salovey and Williams-Piehota, 2004).

Abstract

Quasi-experimental designs (QEDs) are a subset of research designs intended to test causal hypotheses about the effect of manipulable causes, generally policies, programs, and treatments, when randomized controlled trials are not feasible. This article provides a summary of efforts to assess the validity of QEDs to provide unbiased causal inference as well as an overview of the most prevalent types of QEDs used in practice, including regression discontinuity designs, comparative interrupted time series, and nonequivalent comparison group designs.

Quasi-experimental designs (QEDs) are a subset of research designs intended to test causal hypotheses about the effect of manipulable causes, generally policies, programs, and treatments. QEDs are primarily defined by what they are not: experiments, also known as randomized controlled trials (RCTs). In the simplest case, RCTs randomly assign units to either receive a treatment (the treatment group) or not receive the treatment (the control group). Random assignment ensures that the treatment and control groups will be roughly equal as long as the groups are of sufficient size. As a result, the impact of the treatment may be measured by simply taking the difference of the average outcomes of the treatment and control groups, although more complex statistical methods are sometimes used to increase the precision with which the treatment effect is measured.

QEDs differ from RCTs in that units (e.g., individuals, schools, communities) are not randomly assigned to treatment conditions. Rather, units self-select into treatment or are assigned to treatment by program administrators through some nonrandom process. As such, unlike in the case of random assignment where the treatment and control groups are equivalent in expectation, units that receive the treatment and those that do not (often called comparison units in the QED literature) may not be comparable before the treatment begins. Simple comparisons of the outcomes of treated and untreated cases will confound any initial differences with any actual treatment effects. Therefore, researchers using nonexperimental data must carefully identify plausible alternative explanations of the apparent effect and rule them out using logic, design, and measurement (Shadish et al., 2002). However, QEDs may be feasible when RCTs are too costly, unethical, or politically unpopular.

Approaches to Assessing the Validity of QEDs

Quasi-experiments actually predate the use of RCTs in the social sciences, but it was not until the 1950s that Donald T. Campbell and his colleagues began to formalize the notion of quasi-experimentation (Campbell, 1957; Campbell and Stanley, 1963; Cook and Campbell, 1979; Shadish et al., 2002). The cornerstone of this formalization is a validity typology and the systematic categorization of the associated threats to validity. Validity is understood here as, "the approximate truth of an inference" (Shadish et al., 2002, p. 34). Campbell initially ascribed two types of validity to QEDs. A quasi-experiment is internally valid if it can demonstrate whether the relationship between a treatment and an outcome is causal. A quasi-experiment is externally valid if the causal relationship is true across units, treatments, outcomes, settings, and times (Campbell, 1957; Campbell and Stanley, 1963). The validity framework was later expanded to include construct validity (the validity with which the operations within a particular study appropriately represents that, which it was intended to represent) and statistical conclusion validity (the validity of the correlation between the treatment and the outcome). Of these four types of validity, Campbell saw internal validity as most important, arguing that without internal validity, the other validity types were of little consequence (Cook and Campbell, 1979; Shadish et al., 2002).

Campbell went on to articulate potential threats to each type of validity in practice. These threats can be thought of as alternative explanations or plausible alternative hypotheses for an apparent treatment effect, which could render causal conclusions completely or partially incorrect. The initial list of threats, articulated by Campbell in 1957, included eight threats to internal validity and four threats to external validity. By 2002, the list had grown to include 37 threats (Shadish et al., 2002). The goal of strong quasi-experimentation is to retrospectively, and more importantly proactively, analyze and prevent plausible threats to validity through the inclusion of design features in a quasi-experimental (QE) study. In doing so, the list of threats to validity developed by Campbell and his colleagues serve as a heuristic tool to ensure that possible threats are considered and addressed.

Another important approach for understanding causal inference that is useful for assessing the validity of QEDs is the Rubin causal model, or the potential outcomes model, developed by Donald Rubin and colleagues. This model characterizes causal effects as unit-specific differences between the outcomes that would be achieved under different treatment conditions and provides a clear theoretical rationale for the conditions under which observational studies can produce unbiased estimates of causal effects (Rubin, 1978; Holland, 1986; Neyman, 1935; Heckman, 1979). Under this framework, each unit is characterized by a set of variables ($Y_i(1)$, $Y_i(0)$, X_i, T_i), where $Y_i(1)$ is the potential outcome for the ith unit after having received the treatment, $Y_i(0)$ is the potential

outcome for that same unit had it not received the treatment, X_i is a vector of baseline characteristics, and T_i is an indicator of treatment receipt such that $T_i = 1$ if the ith unit received the treatment and $T_i = 0$ if the unit received the control condition. While values of $(T_i, X_i,)$ are observable for every member of the population, only one of the two potential outcomes $(Y_i(1), Y_i(0))$ can be observed for any single individual. The observed outcome for each unit is formally given as: $Y_i = (1 - T_i) Y_i(0) + T_i Y_i(1)$. However, the *unobserved, counterfactual* potential outcome represents what this treatment recipient's outcome *would have been* if she/he had experienced the alternative treatment. Every unit in the population is missing one of these two potential outcomes and this means that we can never directly measure a treatment–control contrast at the unit level. It should be noted that this formulation of the problem implicitly assumes that each units' potential outcomes depend only on whether or not that individual receives the treatment, not on the treatment assignment of other units. This critical assumption, commonly known as the Stable Unit Treatment Value Assumption, is what makes the desired causal quantity, $Y_i(1) - Y_i(0)$, tractable as a simple mean difference.

While the missing potential outcomes make it difficult to estimate individual treatment effects, it is possible to estimate average group differences. In an RCT, randomization assures potential outcomes are missing at random, so the average treatment effect (ATE), $E[Y_i(1) - Y_i(0)]$, can be estimated using the difference in mean outcomes in the treatment and control groups. Put another way, randomization ensures the mean of those treated cases that we observe, $\overline{Y_i(1)}$, is an unbiased estimate of the potential outcome of $E[Y_i(1)]$ for the population. In the case of QEDs, however, the researcher has no such assurance. Instead, he or she must adopt additional assumptions to estimate average causal effects. We will explore the assumptions needed in several common QED designs below using Rubin's potential outcomes framework.

Both Campbell and Rubin provide a theoretical framework for assessing the validity of QEDs, but one may ask whether these approaches produce trustworthy causal inference in practice. Within study comparisons (WSCs) have been increasingly used to address these questions. WSCs compare results from a QED and RCT that shared the same treatment group. The first WSCs drew on data from RCTs designed to study the effects of job training programs. QE estimates of the same treatment effects were calculated by drawing on extant data sets like the Current Population Survey or the Panel Study of Income Dynamics, and statistical adjustment procedures were then used to determine whether various QE methods would replicate the RCT's causal estimate. The early conclusions were that none of these data analytic adjustment techniques were successful (LaLonde, 1986; Fraker and Maynard, 1987; Friedlander and Robins, 1995; summarized in Glazerman et al., 2003). However, these early WSCs had RCT and QE units that differed in many ways other than whether the comparison group was formed at random or not – the key independent variable of a WSC. In some cases, the comparison units were drawn from distant locales and measured at different times on different scales than in the RCT benchmark. Later studies took more pains to draw comparisons from the same target population as the RCT, that shared the same geographic location, and that were measured at the same time and on the same scale. They also moved beyond asking whether QED methods could replicate RCT results and came to focus instead on the conditions under which QED and RCT methods generated similar causal results. There is now an increasing number of WSCs that have been conducted across domains and have begun to provide empirical evidence on the validity of various QEDs in practice. Key findings from the WSC literature are included in the discussions below.

Types of QEDs

Although there are many types of QEDs, the most commonly used designs include regression discontinuity designs (RDDs), interrupted time series (ITS) and comparative ITS (CITS) designs, and nonequivalent comparison group designs.

Regression Discontinuity Designs

RDDs are used to estimate the effect of a treatment that is assigned based on a threshold for a continuous variable. For instance, students may be assigned to a remedial educational program if they score below a certain cutoff score on an assessment. The use of a threshold for treatment assignment produces a discontinuity in the probability of treatment, which, in the presence of a treatment effect, leads to a discontinuity in outcomes. RDDs assume that units just above or below the threshold are roughly equivalent, and estimate a treatment effect by comparing the outcomes of these two groups. RDD was used infrequently after the original conceptualization in 1960 by Thistlewaite and Campbell, but recently has received increased attention (Cook, 2008; Lee and Lemieux, 2010). The design is now designated as the preferred QED by the Institute of Education Sciences when an RCT is not possible (Schochet et al., 2010), reflecting a widespread belief that it is among the most rigorous of the QEDs (Cook and Wong, 2008).

RDD estimates the counterfactual based on units close to but not meeting the threshold for treatment. The simplest case is a 'sharp' RDD, in which the probability of treatment is completely determined by the threshold of an ordinal or continuous variable, referred to as the 'forcing' variable: $T_i = 0$ if $Z_i < z_c$ and $T_i = 1$ if $Z_i > z_c$ (or the reverse). Suppose that the outcome of unit i depends on the treatment (This approach follows Hallberg et al. (2013); see also Imbens and Wolldridge (2008) and Lee and Lemieux (2010).):

$$Y_i = \begin{cases} Y_i(1) + \varepsilon_i, & T_i = 0 \\ Y_i(0) + \vartheta_i, & T_i = 1 \end{cases}$$

As above, $Y_i(0)$ is the outcome in the absence of treatment, $Y_i(1)$ is the outcome in the presence of treatment, and ε_i and ϑ_i are random error terms. The treatment effect to be estimated is the difference in potential outcomes at the threshold value $\tau = E(Y_i(1) - Y_i(0)|Z_i = z_c) = E(Y_i(1)|Z_i = z_c) - E(Y_i(0)|Z_i = z_c)$. Only one of these potential outcomes is observed at the cutoff. Therefore, outcomes for units close to this cutoff are used instead, and the treatment effect is $\tau = \lim_{z \downarrow z_c} E(Y_i(1)| Z_i = z) - \lim_{z \uparrow z_c} E(Y_i(0)|Z_i = z)$.

'Fuzzy' RDD occurs when the threshold of the forcing variable influences but does not completely determine treatment assignment. In this case, the treatment effect is the ratio of the discontinuity in the outcome to the discontinuity in the treatment $\tau = [\lim_{z \downarrow z_c} E(Y_i(1)|Z_i = z) - \lim_{z \uparrow z_c} E(Y_i(0)|Z_i = z)]/[\lim_{z \downarrow z_c} E(T_i|\ Z_i = z) - \lim_{z \uparrow z_c} E(T_i|Z_i = z)]$. This setup is similar to an instrumental variables approach in which the forcing variable is an instrument for treatment assignment.

For the RDD treatment effect estimates to be internally valid, there can be no discontinuity of potential outcomes at the cutoff (Hahn et al., 2001). If potential outcomes – that is, f_0 or f_1 – were not smooth at the cutoff, this would suggest that other factors also influenced the outcome based on whether the forcing variable met the threshold value. RDD estimates would then confound the effects of the treatment with the effects of these other factors. For instance, if a threshold determined eligibility for two programs, RDDs would not be able to distinguish between their respective effects. Actors manipulating the forcing variable in order to control selection into or out of the treatment may also create discontinuities in potential outcomes that could affect the internal validity of RDD estimates. Tests for discontinuities in the forcing variable or other covariates can provide evidence on whether the continuity restriction holds, although they cannot provide definitive proof (McCrary, 2008).

RDD estimates may also be biased by incorrect assumptions about the relationship of the outcome and the forcing variable at the cutoff. Nonparametric estimation is possible but requires many data points near to the cutoff, which may not be available in practice (Wing and Cook, 2013; Schochet, 2008). Assuming that the relationship takes a specific functional form can support estimation in these cases, but incorrect assumptions will bias estimates. Therefore, weaker or more flexible functional forms are generally favored, such as polynomial functions or local linear regression (Imbens and Lemieux, 2008; Hallberg et al., 2013). Another consideration is how close data points must be to the cut point to be included in the analysis, referred to as the 'bandwidth.' Some approaches to choosing bandwidth have been proposed (Ludwig and Miller, 2005; Imbens and Lemieux, 2007; Imbens and Kalyanaram, 2008), with cross-validation as an important robustness check (Hallberg et al., 2013; Imbens and Wolldridge, 2009). (A further consideration for local regression methods is the choice of the kernel. However, Imbens and Lemieux (2008) argue that because results not robust to the choice of kernel would be unconvincing, there is little benefit to using kernels more complex than a uniform distribution.)

The external validity of RDD estimates is limited because the design focuses on the outcomes of units near the threshold. RDDs estimate a local average treatment effect (LATE) that applies to units assigned to treatment because of the threshold, rather than a general ATE across all units. For sharp RDD, this includes all units close to the threshold. For fuzzy RDD, this includes units close to the threshold who were induced to either take up or abstain from the treatment as a result of their score on the assignment variable, referred to as 'compliers.' The LATE and ATE will differ if treatment effects vary based on the value of the forcing variable.

WSCs have generally found that RDDs can reproduce experimental estimates of LATE estimates. These studies generally restricted experimental samples to units close to the cutoff to estimate the LATE to find general, though not universal, agreement between the two methodologies (Aiken et al., 1998; Buddelmeyer and Skoufias, 2003; Black et al., 2005; see Cook and Wong, 2008 for a review). An additional WSC compared an RDD estimate of the LATE to an RCT estimate of the ATE for units below the cutoff, also finding similar results (Berk et al., 2010). Shadish et al. (2011) randomized units into two different treatment assignment mechanisms, random or cutoff-based. They compared RCT estimates of the former with RDD estimates of the latter, finding general agreement between the two. Wing and Cook (2013) propose adding a pretest measure of the outcome or a comparison group to the RDD. Using a WSC, they find that this can improve the precision, internal, and external validity of RDD estimates.

Comparative ITS Designs

ITS designs estimate a program's effect by comparing an outcome for a treatment group before and after the beginning of a program. Change in the outcomes at the time of the intervention is attributed to the program. CITS approaches add a comparison group to address the possibility that the change in outcomes was due to factors other than the treatment, assuming that these other factors affected the treatment and comparison groups equally.

ITS models estimate the counterfactual by modeling past trends in outcomes and projecting them into the future. Suppose that the outcome of unit i depends on both time t and treatment T_i, such that (This approach follows Wong et al. (2013).):

$$Y_{it} = \begin{cases} f_0(t) + \varepsilon_{it}, & T_i = 0 \\ f_1(t) + \vartheta_{it}, & T_i = 1 \end{cases}$$

Here, f_0 is the course of the outcome in the absence of treatment, f_1 is the course of the outcome in the presence of treatment, and ε_{it} and ϑ_{it} are random error terms. The treatment effect to be estimated is the difference in potential outcomes, $\tau(t) = f_1(t) - f_0(t)$. ITS capitalizes on the fact that parts of both functions are observed before or after the time of treatment, t_c. Before treatment ($t < t_c$), f_0 is observed; after treatment ($t > t_c$), f_1 is observed. The change at the time of treatment is used to estimate the treatment effect; in this way, ITS is similar to an RDD in which time is the forcing variable. As with RDD, a key assumption is the functional form of the outcome around the time of treatment. Bloom (2003) provides a summary of different modeling approaches.

For the ITS treatment estimate to be causal, no factors other than the treatment contribute to the change in outcomes at the time treatment occurs. ITS estimates will be biased in the presence of such simultaneous effects, which may be due to history, selection effects, or instrumentation (Shadish et al., 2002). A comparison group may be added in an attempt to rule out such confounding effects. CITS designs benchmark the change in the treatment group against the change in the comparison group. Here, the *change* in outcomes for the comparison group at the time of treatment serves as the counterfactual for the change in outcomes for the treatment group. Still, any factors

other than the treatment that lead to different changes in outcomes at the time of treatment for the two groups will still cause bias in CITS estimates. The selection of comparison cases therefore becomes an important consideration for CITS.

A modest but growing body of work seeks to examine the validity of ITS analyses through WSCs comparing their estimates to those from experimental designs. Multiple studies have found that ITS or CITS analyses can produce estimates similar to those from RCTs (Schneeweiss et al., 2004; Shadish et al., n.d.; Fretheim et al., 2013; St. Clair et al., 2014) or RDDs (Somers et al., 2012). However, evidence suggests that the validity of ITS analyses depends on the context of the intervention. For instance, St. Clair et al. (2014) find that misspecification of functional form can produce bias in the presence of linear trends in outcomes over time.

Nonequivalent Comparison Group or Matching Designs

When random assignment is not feasible, researchers often seek to identify comparison units that are similar to those receiving the treatment to approximate a randomly assigned control group. While randomization to ensure that the observed treated and control case are similar in both observed and unobserved ways, matching approaches rely solely on comparing treatment and comparison cases that are equivalent on all *observed* characteristics. As such, matching approaches rely on a critical assumption known alternatively as the strong ignorability assumption, the nonconfoundedness assumption, or the conditional independence assumption. This assumption states that

$$Y_i(1), Y_i(0) \perp T_i | \boldsymbol{x_i}$$

That is, matching approaches can produce unbiased causal inference if the potential outcomes are independent of treatment receipt controlling for observed characteristics. If this assumption holds, Rosenbaum and Rubin (1983) show that, at each value of $\boldsymbol{x_i}$, the difference between the treatment and control means is an unbiased estimate of the ATE at that value. If there are both treated and untreated cases $(0 < \mathrm{P}(T = 1|\boldsymbol{x}) < 1)$ for every value of $\boldsymbol{x}$, then we are able to use matching methods to estimate the ATE for the population. If this 'common support' or 'overlap' assumption fails, causal inference is limited to the values of $\boldsymbol{x}$ in which there are both treatment and comparison cases, the region of common support.

In the absence of complete knowledge of treatment assignment process, there are often a large number of pretreatment covariates that could ostensibly influence selection into treatment and the outcomes of interest. In these cases, it is often difficult to find exact matches on each of a wide array of covariates. To address this 'curse of dimensionality,' Rosenbaum and Rubin (1983) introduced propensity score approaches. The propensity score is defined as the conditional probability of treatment receipt given a vector of observable characteristics:

$$e(x) = P(T_i = 1|\boldsymbol{x}_i)$$

The propensity score is often estimated using a logit or probit model to calculate each case's expected probability of treatment given the observable covariates. Rosenbaum and Rubin show that adjustment on the basis of the estimated propensity score is sufficient for removing bias due to all observed covariates. As such, if strong ignorability is met, propensity score adjustment, whether through case matching or stratification, can provide unbiased estimates of causal effects.

Critically, it is impossible to test the strong ignorability assumption empirically. Rather, researchers must rely on substantive theory to determine the plausibility of whether all of the potential confounding variables (those correlated both with selection into treatment and the outcome) have been observed (Rosenbaum and Rubin, 1983).

Qualitative syntheses of WSCs to date have suggested at least three promising cases in which observational approaches seemed to perform well: (1) when researchers condition on pretreatment measures of the outcome of interest (Glazerman et al., 2003; Bloom et al., 2005; Smith and Todd, 2005; Bifulco, 2012); (2) when a rich and reliable set of pretreatment covariates are available (Cook et al., 2008; Shadish et al., 2008; Steiner et al., 2011), and (3) when matches are geographically local (Friedlander and Robins, 1995; Bell et al., 1995; Heckman et al., 1998; Bloom et al., 2005; Bifulco, 2012).

Conclusion

QEDs use logic, design, and measurement to estimate causal effects of programs and policies when RCTs are not possible or feasible. A rich body of literature provides theoretical guidance on the conditions under which sound causal inference is possible in QEDs. Further, a growing number of WSCs have been conducted and are beginning to provide practical guidance to applied researchers implementing these research designs. Findings from these WSCs suggest that RDD, CITS, and some kinds of matching designs *can* replicate experimental findings in practice. More studies are needed to examine how replicable these findings are across contexts and fields. Additional WSC studies that consistently probe the conditions under which QEDs can provide trustworthy results are needed, especially in the area of nonequivalent comparison group or matching designs. Much of this work is currently underway across a variety of venues and we expect that in a few years, even more practical guidance will be available to applied researchers.

Abstract

This article briefly draws out some historical and contemporary relationships among queer and anarchist theories and practices, highlighting the rise of a distinctive form of queer anarchism.

This queer anarchism has roots in the earliest anarchist theorists who, like contemporary queer theorists, saw clear links between hierarchies of political economy and rigid constructions of the individual (e.g., vis a vis gender and sexuality). Drawing strength from roots in the overlaps and differences in queer and anarchist traditions, queer anarchism offers cultural, analytical, and practical tools for addressing contemporary challenges to individual and collective freedom, equality, and vitality.

Queer anarchism is a term arising in recent years to signify the overlaps, affinities, and mutual influences between queer and anarchist traditions of theory and practice. Queer theory emerged in the early 1990s inspired by the work of key figures including Judith Butler, Gloria Anzaldua, Eve Sedgwick, Michel Foucault, and Audre Lorde. Noted for its critique of fixed identities, a decentralized understanding of power and an intersectional analysis of oppression, queer theory deconstructs conventional ideas of politics in order to make space for new forms. Soon after, anarchism reemerged on the global stage with the 1999 Battle of Seattle where a loose coalition of anarchists, feminists, labor organizations, environmentalists, and others shut down the World Trade Organization Ministerial Conference. Anarchist(ic) methods of scholarship, horizontal organizing, direct action, and direct democracy played a key role in the success of the protests and continue to do so in the ongoing global social justice movements (e.g., Occupy, the Arab Spring, Idle No More, Zapatismo, and many more) (Bray, 2013; Day, 2005; Gordon, 2008; Kinna, 2012). Both of these seemingly disparate traditions have shared roots in the student/worker uprisings of May 1968, in feminist and queer movements including those which parallel anarchist critiques of hierarchy (e.g., AIDS Coalition to Unleash Power (ACT UP) and Greenham Common Women's Peace Camp), and in a variety of theoretical developments as noted above (Heckert and Cleminson, 2011a). Recognition of these shared roots and the resultant affinities between the critique of normativity in queer theory and activism and anarchism's critique of hierarchy, as well as actually existing queer/anarchist movements (Brown, 2007) and cultural productions (Keenaghan, 2008; Nyong'o, 2009) have inspired the ascendance of a distinctly queer anarchism (Daring et al., 2012; Heckert, 2010; Heckert and Cleminson, 2011b).

A Queer History of Anarchism

Queer theory and anarchism might seem like an odd match to some, given their different intellectual trajectories. Anarchism is often associated with the Enlightenment project of progressive modernist politics; as a class struggle movement to revolutionize society, overthrow capitalism and the state, and institute new social relations based on the common ownership of society in a stateless form of democratic and participatory socialism (Schmidt and Van der Walt, 2009). If one accepts that way of narrating anarchism, then queer theory might, indeed, seem at odds with anarchism. Queer theory, after all, is typically associated with the *post*modern condition and post-structuralist theory. Post-structuralism is often described as *critiques* Enlightenment politics, progressive views of history, and what were, according to many of post-structuralism's advocates, the essentialist politics and grand narratives mobilized by the radical theories of the modern era. Yet many contemporary anarchists are drawing productively on post-structuralist theory, some even sketching out what has come to be called *postanarchism* (Rousselle and Evren, 2011). In many ways, anarchism *anticipated* some of the arguments within post-structuralism broadly and queer theory specifically, providing the roots of what came to be called 'queer anarchism.'

Foucault's (1977a, 1977b, 1980, 1991) critique of a particular Marxist reduction of power to economics and his consequent analysis of decentralized micropolitical forms of disciplinary power, including specifically in the realm of sexuality, was essential to the development of queer theory. In this, Foucault was long preceded by anarchists in the late nineteenth and early twentieth centuries who were also explicitly attentive to institutions like the state and other forms of oppression. The anarcho-syndicalist, Rudolf Rocker, held "that the war against capitalism must be at the same time a war against all institutions of political power," because "exploitation has always gone hand in hand with political and social oppression" (Rocker, 2004: p. 11). Likewise, the Italian anarchist, Errico Malatesta (1920) suggested a *reciprocal* relationship between people and institutions (rather than seeing the economic structure as being 'the real foundation' of social existence): "Between man [sic] and his social environment there is a reciprocal action. Men make society what it is and society makes men what they are, and the result is therefore a kind of vicious circle. To transform society men must be changed, and to transform men, society must be changed."

Similarly, early anarchists often saw their *technique* differently, as a way of acting on/in the world that tended to stress relationality rather than simply a struggle between the workers and the owners of society. This relationality is perhaps best embodied in a quote by the German anarchist, Gustav Landauer (Kuhn, 2010: p. 214), when he argued that "the state is a social relationship; a certain way of people relating to one another. It can be destroyed … by people relating to one another differently." Landauer (Kuhn, 2010, emphasis in original) argued passionately that "(t)he entire system would vanish without a trace if the people began *to constitute themselves as a people apart from the state*." Landauer wrote these words in 1910, yet they have a striking resemblance to contemporary radical theories influenced by post-structuralism that advocate a strategy of exodus out of capitalism. For a queer anarchist approach, the queer critical emphasis on forces of normalization and normativity derived from Foucault and others is the flip side of the anarchist emphasis on hierarchy. At the same time for many anarchists (e.g., Emma Goldman), normalization, uniformity, and sameness were recognized as fundamental to the constitution of authoritarianism. While Foucault refused to align himself with any political identity or tradition, he did acknowledge that his efforts to understand power and the state constituted a form of anarchaeology, taking no power as necessarily to be accepted (Day, 2005).

Transformations of social relations and the challenging of normativity and various forms of power have long included those *within* anarchist movements. Gender norms and relations offer a prime example. Some anarchist men saw "the issue of women's subordination as, at best, secondary to the emancipation of workers, a problem that would be resolved 'on the morrow of the revolution'" (Ackelsberg, 2005: p. 38). Ackelsberg (2005: p. 21) painstakingly outlines the efforts of the Mujeres Libres, an anarchist women's group that "mobilized over 20 000 women and developed an extensive network of activities designed to empower individual women while building a sense of community" during the Spanish Civil War of the early twentieth Century. Ackelsberg (2005: pp. 21, 37) notes that the Mujeres Libres were "dedicated to the liberation of women from their 'triple enslavement to ignorance, as women, and as producers'" largely adopting a theory of anarchism that "insisted that power has its own logic and will not be abolished through attention to economic relations alone." It was quite common for early 'classical' anarchists including Peter Kropotkin, Emma Goldman, and Voltairine de Cleyre to write about (and organize around) issues such as prostitution and sex trafficking, forced sterilizations, and marriage, widening the anarchist critique of hierarchy to give critical concern to women's issues in their own right.

Perhaps more to the point for *queer* anarchism, this was certainly true of anarchist theorizing and organizing around sexuality specifically (though both 'queer' and 'queer anarchism' frequently engage in intersectional analyses and practices not limited to gender and sexuality). Early anarchists had a noted role in a radical politics of same-sex relationships, stressing human freedom and emancipation from repressive sexual norms that saw same-sex love and sexuality as unnatural, sinful, and subordinate (Kissack, 2008). Nearly a century before queer theory's declarations of the limits of identity, Emma Goldman noted that sexual identities cannot (honestly) bound the huge variety of individual experiences of gender and sexuality, that "[i]t is a tragedy, I feel, that people of a different sexual type are caught in a world which shows so little understanding for homosexuals, is so crassly indifferent to the various gradations and variations of gender and their great significance in life" (in Katz, 1976: pp. 378–379). Queer anarchism is committed to a recognition of difference, both through honoring self-determination of gender and other identities (Stanley and Smith, 2011) and by encouraging sabotage of, playfulness with, or nonattachment to, identity (Heckert, 2013; Sallydarity, 2012). Similarly, many early anarchists advocated free love, same-sex love, and support for sex workers (Kissack, 2008). Like queer theory, the politics of the historical anarchist tradition was often relational, creative, and not centered solely on class and those politics expanded beyond humanity's interactions and relationships with each other. Bookchin (1977), for example, notes how anarchists during the Spanish Civil War often experimented with nudism, vegetarianism, and relating differently with the land underneath their feet. Early anarchists also saw a need for developing new relationships with the Earth, nonhuman animals, and even their notion of *selves*. We might also note that like today's queer theorists, anarchist figures such as Emma Goldman, among many others less famous, were also engaged in discursive forms of activism through public talks and writing, which included what today would be called cultural studies (Ferguson, 2011).

Similarly, early anarchists frequently put forward ideas about enacting anarchy that did not follow the progressive politics of radical modernist perspectives. While some radicals argued for communism as an end of history, following discrete stages of development in society (particularly Marx), many early anarchists did not see a clear beginning nor end to their project. Malatesta (1920: p. 75) famously declared that the point was "not whether we accomplish Anarchism today, tomorrow, or within 10 centuries, but that we walk toward Anarchism today, tomorrow, and always." Emma Goldman (1972[1908]), likewise, stated that what she believed in was "a process rather than a finality. Finalities are for gods and governments, not for the human intellect."

One might look, then, for the historical beginnings of queer anarchism within the early anarchist movement around the turn of the nineteenth Century. Anarchism anticipated many of the arguments developed by contemporary theorists of post-structuralism and queer theory. Early anarchists were often quite critical of theories of society that reduced complex human interactions to simple economic functions. They held radical views of gender and sexuality, noting a wide range for gender and sexual practices. They saw a need for relational politics, often in addition to theoretical models of class struggle, which stressed a need to develop new relationships with each other, our selves, and the entire nonhuman world. And rather than narrating history and the future as a series of stages of development with a discrete end to political struggle, many early anarchists stressed anarchism as a process – as an experience – with no definite end. These connections allow us to stress very early relationships between *queer* and anarchism that can, perhaps, problematize the notion that queer anarchism is a particularly *recent* phenomenon.

From those early roots to today, the anarchist tradition is rich in resources for radical queer theory and politics. Anarchist

polymath Paul Goodman, for example, was one of the first intellectuals to publicly reclaim the word queer. Daniel Guerin linked the politics of a hetero/homo divide to wider questions of political economy. Gay and Women's Liberation Movements from the 1970s used anarchic methods in attempts to organize as free equals. Anarcha-feminists around the world including Peggy Kornegger, Takamure Itsue, Mujeres Creando, and many more engage(d) with the intersections of gender, sexuality, and other hierarchies. Anarchist novelists including Ursula LeGuin, Marge Piercy, and Starhawk queer gender, sexuality, and authority. ACT UP, who inspired later queer theorists, developed nonhierarchical methods later taken up by alter-globalization activists. Greenham Common was a site of queer anarchist activism effectively challenging militarism, patriarchy, and compulsory heterosexuality. In each of these cases, critics note that nonhierarchy was often not as well implemented as it might have been. Oppressive practices can still occur within spaces declared anarchist or queer. Anarchist ideals are high and living up to them is an incredible challenge. One of the key challenges anarchism attempts to put into practice, and therefore brings to queer theory, is the task of combining individuality *and* community, or, in other words, making space for difference while being able to live well together. Indeed, contemporary queer theorists including Judith Butler, Lauren Berlant, and Judith Jack Halberstam are increasingly influenced by explicitly anarchist and autonomist movements including Occupy (transnational), Anarchists Against the Wall and Black Laundry (Israel/Palestine), Pink Panthers (Canada), Queeruption (transnational), Church Ladies for Choice (USA), Proyectil Fetal (Argentina), Mujeres Creando (Bolivia), and other queer anarchists groups.

Queering Identity/Politics

Queer theory and politics arose, in part, as diverse responses to sexual identity politics that were based on a centralized understanding of sexual orientation and gender identity functioning as a truth of the self. This understanding lends itself to a state-centered politics of formal equality under the law through the liberal discourse of human or civil rights (Conrad, 2012; Liesegang, 2012; Lydon, 2012). In this situation, a feedback loop can develop whereby attempts to become comprehensible to the gaze of the state encourages a statelike interpretation of gender and sexuality: both are assumed to be static, fixed, and conforming to clear borders (Carr, 1999; Heckert, 2011a; Stanley and Smith, 2011). The strategy is highly successful for some Lesbian, Gay, Bisexual and Transgender (LGBT) people and in certain terms. However, a queer approach, whether in the university, the streets or across/outside any such division, questions the meaning and cost of institutionalized 'success' and offers alternatives (Against Equality, 2013; Brown, 2011; Heckert, 2011b; Jeppesen and Nazar, 2012; Roseneil, 2000).

Insider/Outsider

The first question of a queered identity/politics might be, who ends up outside the borders of identity politics? When politics is defined in terms of state citizenship, there will always be outsiders. Bisexual people, for example, are often labeled in statist terms (e.g., tourist, traitor, criminal, and spy) for not conforming to a hetero/homo border. Transgender, too, can trouble tidy borders of male/female, hetero/homo placing it lower down the sexual minority hierarchy. In addition, the politics of race, class, nationality, and other social divisions are often defined as 'outside' a politics of gender and sexuality. In statist thought, these are all separate categories, separate issues. In lived life, as feminism by women of color has brought to queer theory and to anarchism, oppressions intersect. When sexual politics is imagined to be separate from race or class, it simply means that it is associated with racial and class privilege. In statelike politics, it is those placed on the outside of the border or at the bottom of the hierarchy, which are simultaneously constructed as *having* the problem and as *being* the problem. In a queer anarchist politics, it is the border/hierarchy itself, which is in question. Where identity politics focuses on issues, such as marriage, the military, and other examples of equality within institutions, queer anarchism asks what exclusions, what violence, results from hierarchical institutions? Anarchist groups are more likely to focus campaigns on gentrification, state violence, homo nationalism, queer youth homelessness, sex work, health care, and other issues disproportionately affecting working class and/or queers of color.

Equality

An intertwined query concerns the nature of equality. In state-centered discourse, this refers to formal equality under the law. Queer and anarchist commentators may ask what inequalities are *produced* by law. For example, the legal construction of private property, including that claimed by the legal fictions known as corporations, is fundamental to maintaining local and global inequalities in access to the Earth's common resources including food, fuel, medicine, clean water, land, information, and more. When such a situation is discursively constructed as normal, any politics, which questions its legitimacy is clearly queer. Moreover, anarchism queries the inequality of a small group of people creating laws for entire populations. In anarchism, equality is not a formal matter, a practical one. In practice, how do we learn to relate freely as equals? 'With practice,' anarchist and other traditions show. This includes various forms of direct action and collective decision making, rather than representative democracy, whereby members of collectivities learn to collectively make decisions themselves in order to live, work, and play as free equals. Significantly, for queer anarchism, relating as equals also applies to romantic, sexual, familial, pedagogical, friendly, and other relations deemed to be outside the liberal political sphere.

Queering Representation

This critique of the state as institution is embedded within a broader and deeper questioning of the emphasis placed on representation. Where Deleuze (Foucault, 1977c) spoke of 'the indignity of speaking for others,' queer anarchism might emphasize the dignity of listening. Where many mainstream LGBT equality organizations lobby governments and other bodies by claiming to speak for a minority population, queer

anarchist approaches emphasize a decentralized bridging methodology. Groups form in order to directly address the concerns of their members and network horizontally with other groups also facing oppression. Through cooperation and listening, mutual transformations occur, personal connections are formed, collective lessons are learned, and practical grassroots work addressing social–ecological needs is undertaken. Where institutional success is frequently measured in terms of organizational longevity and measurable outcomes, a queer anarchist approach recognizes the value of experimentation, temporary structures, evolving networks, and cultural shifts imperceptible to the distant biopolitical gaze of the state.

The State of Sexuality

Not only does queer anarchism query speaking for LGBT people, it also asks how the very idea of 'LGBT people' acts as a limiting form of representation. For example, one queer anarchist formulation (Heckert, 2011a) reads sexual orientation as a prime example of Deleuze and Guattari's 'state form.' For Deleuze and Guattari, like Landauer mentioned above, the state is not merely a distant institution but a social pattern replicated at micro- as well as macrolevels. As an institution, it depends upon the reproduction of statelike relationships throughout society. These relationships are characterized by overcoding. If coding is a linguistic necessity, labeling objects in order to communicate about them, overcoding is the reification of those codes, categories, labels over, and above the diversity and complexity of lived experience. In other words, it prioritizes representation over direct relationship, fixity over fluidity, and judgment over compassion. By looking at the statist nature of gender and sexual normativity, queer anarchism acts *to queer* anarchism. By linking normativity to hierarchy, queer anarchism highlights the anarchic impulse within queer theorizing and organizing.

Compassionate Self-Inqueery

Queries regarding equality and representation might also be referred reflexively, compassionately applied by queer anarchist groups to themselves. There is always the potential of queer anarchism to transform from the process of questioning, experimenting, and experiencing into the reified fantasy of itself as a superior identity position (a form of representation). This may be defined as smarter than more mainstream LGBT movements, more socially engaged than queer theorists or more sexy than other anarchists. While disdain or resentment toward movements that hurt, invisibilize or exclude can be effective mechanisms for avoiding pain, disconnecting from the experience of being alive (including pain) can make the practice of liberty, equality, and vitality impossible. Thus, an effective queer anarchism looks not only at external relations but also at one's own relationships with beliefs, desires, emotions, and embodiment. Recognizing these relations as the effects of social conditioning, they need to be seen to represent the judgmental truth of oneself as is encouraged in a society of control. Rather, some might be perceived as patterns helpful for surviving a hierarchical society and helpfully released for building an anarchist one. Queer and/or anarchist is not a state of being but a continual process of becoming. In this sense, then, queer anarchism can help create a form of self-reflexivity that does not rely on blame (toward self or others), but instead looks to understand the external social basis for all of our beliefs, desires, and feelings. Instead of fault, the focus, then, looks toward transformation (creative and destructive).

Queering Anarchism

Queering functions to keep topics of gender and sexuality, emotion and embodiment, and love and desire on the anarchist map. It does so by highlighting the relevance of diverse issues related to sexual categorization and beyond (including Bondage & Discipline; Dominance & Submission; Sadism & Masochism (BDSM), sex work, non/monogamy, pregnancy, gender diversity, asexuality, sex education, communication skills, bodily practices of freedom, and more) to the continuous production of borders and hierarchies, as well as to practices of collective decision making, community building, and libertarian political economy. Queer anarchist methods include creative direct action, cultural productions, radical pedagogy, social research, cultural studies, subtle interventions into dominant patterns, cultivating self awareness, carving out queer autonomous spaces, and various forms of playful subversion. Queering also functions to keep anarchism from becoming that which it aims to replace. In addition to playing with diverse subjects and methodologies, queering anarchism involves experimenting with the meaning of anarchism itself. Anarchism, like any ideology, has the potential to become rigid, sectarian, and abstracted from lived experience. Queering, as an ongoing process of loosening borders, playing with identities, and accepting uncertainties, can help keep anarchism true to its ideals of equality, vitality, and diversity.

Queer Anthropology

Abstract

Queer anthropology is defined as the analysis of social systems, practices, and symbolic resources in contexts of sexual difference from the (presumed) norms of heterosexuality and gender ascription. This article argues that while the study of sexuality has enjoyed a place in anthropology since its inception, homoerotic or homosexual practices and identities have only relatively recently secured legitimacy as objects of study; this overview of the subfield focuses on queer anthropology's contributions to the discipline of anthropology and to transdisciplinary gender and sexuality studies more broadly.

One might argue that the discipline of anthropology has always been a little bit 'queer.' Historically, it has taken human marginality as its object of study and it has consistently demonstrated that social norms are contingent. It was Malinowski himself after all who insisted that sexuality and sexual practices were not simply vehicles for legitimating (heterosexual) marriage but, rather, a more polysemic set of social behaviors. However, one could also argue that the discipline of anthropology has been quite un-queer. Although the study of sexuality has enjoyed a place in the discipline since its inception, homoerotic or homosexual practices and identities have only recently found legitimacy as objects of study in their own right. As recently as the early 1990s, lesbian and gay studies in anthropology were still being described as an 'emergent field' within the discipline (Weston, 1993). I begin with this paradoxical argument in order to index the ways in which queer anthropology is an uneasy category. As a subfield, or perhaps better put – using the terminology of queer communities – as a 'bent' within the discipline, queer anthropology has been a particularly adaptive genre of inquiry. Queer, same-sex, or lesbian, gay, bisexual, transgender sexuality has never enjoyed the hallowed status of anthropology's hallmark objects of study such as indigenous peoples, kinship dynamics, or political systems. Yet, the subfield has engaged canonical anthropological topics, often reinterpreting their assumptions and providing a queered vantage on classical questions. Provocative new readings on language and kinship that have sought to look beyond heteronormative hegemony, for example, have enlivened debates not only in queer anthropology but in the discipline more broadly.

Queer anthropology can be broadly defined as the effort to examine social systems, practices, and symbolic resources that emerge in contexts of sexual difference from the (presumed) norms of heterosexuality and gender ascription. While queer anthropology has, by definition, contranormative impulses, it is also true that the subfield has struggled to be recognized and legitimated; queer anthropology has had to balance its political, theoretical, and substantive penchant for subversions against conceits that would consign it to triviality, lewd preoccupation, or a 'minority' concern. Like feminist anthropological work that was so foundational to its evolution, queer anthropology is an experimental mode of ethnographic practice. It prides itself on innovative, transdisciplinary engagements and, at times, rather radical departures from the status quo. While 'queer anthropology' is a capacious, contemporary way to describe anthropological work that examines sexual diversity, both ethnographically and theoretically, queer anthropology is also a designation that has its limits and controversies. In order to uncover these contingencies, queer anthropology must be situated in historical perspective and grounded in earlier anthropological studies of sexuality. However, this does not mean defining a linear trajectory from A to Q; instead, the queer anthropological works I overview here will be juxtaposed thematically rather than chronologically, highlighting focal areas of research and key questions that have emerged within the field. With a better understanding of the issues and insights that have animated queer anthropological analysis we can then turn to potential anthropological futures for cultural erotics and sexual imaginaries.

Histories of Sexuality and Queer Paradoxes

Anthropology has never been particularly prudish in its treatment of sexuality. But historically, it has been inclined to engage 'human sexuality' broadly, privileging heterosexual relationships and practices over nonheterosexual ones. In the early twentieth century, Bronislaw Malinowski endeavored to understand sexual practices and nonmarital 'amorous adventures' among the Trobriand Islanders. Margaret Mead was also rather famously fascinated by gender and sexual roles in the South Pacific, including premarital erotic contact among adolescents and Samoans' treatment of *moetotlos* ('sleep crawlers'). Ruth Benedict, one of Mead's mentors and one of anthropology's founding foremothers, suggested that concepts of 'deviance' were relative and contingent upon social circumstances. Her psychologically oriented research offered a challenge to the presumed psychoanalytic 'truth' of sexual deviance that was dominant at the time. It is also a rather open secret that both Benedict and Mead were far from heteronormative in their practices. E.E. Evans-Pritchard's collection of pre-European contact narratives gathered between the 1920s and the early 1960s in southern Sudan among the Azande, was another early surfacing of queer anthropology. Pritchard's discussion of 'male wives' (Evans-Pritchard, 1970) demonstrated how transgenerational and ranked homosexual relationships were founded and maintained in the hypermasculinized social

domains of Azande warriors. He also indicated that female same-sex sexual relationships were (although prohibited) prevalent in polygamous households. However, Benedict's critiques of social deviance models and Evans-Pritchard's 'queer' moment were but two instances within a more general tendency in the discipline to view sexuality through a decidedly heterosexual lens. The Human Relations Area Files (HRAF), for instance, a catalog of ethnographic data from nearly everywhere on the planet, indexed levels of 'sexual promiscuity' as well as levels of 'tolerance for homosexual behavior' within civilizational groups. The HRAF model was symptomatic of a more generalized western fascination with sexual taboos and anxieties about how sexuality operated to stabilize or threaten heterosexual marriage and reproduction. Given the history of western worries about sexuality in general – as a polluting practice, as a dangerous endeavor, and as a sinful preoccupation (Douglas, 1966; Vance, 1984) – anthropology's ability to establish the study of sexuality as a scientifically legitimate project is notable and even laudable. These were the beginnings of analytic perspectives that had the potential to illustrate the diversity of the human condition from the vantage of sexual behavior and sexual sensibilities.

Defining what constitutes 'homosexuality' was, and continues to be, an unsettled question. A relatively early debate in queer anthropology is a case in point. Working with 'the Sambia' (a pseudonym) in Papua New Guinea, Gilbert Herdt (1984) described a series of institutionalized encounters where Sambian boys were expected to ritually fellate their older male mentor. Boys were required to physically ingest the masculine power that resided in a particular fluid: semen. This was, according to Herdt's analysis, how boys became fully socialized men. Herdt's study, unsurprisingly, provoked considerable reaction, in part because it involved sexual partners of different ages. For many western readers, this was a culturally institutionalized form of child sexual abuse. It was a test of anthropological relativism to be sure. But beyond a kind of moral provocation, Herdt's study animated other questions about what specifically constitutes 'sexual' practice and 'homosexual' behavior in particular. Herdt described Melanesian semen ingestion practices as 'ritualized homosexuality,' suggesting that they challenged heterosexual sureties and disputed the cross-cultural reproductive logics of heterosexuality. Deborah Elliston (1995), however, argued against Herdt's interpretation. She claimed that to call these acts 'ritualized homosexuality' was to export a Western model of sexuality to non-Western societies. For Elliston, Melanesian semen practices ought to be understood not through the western category of homosexuality but as a comment upon the value of fluids in Melanesian societies. The debate between Herdt and Elliston, though it may have been limited to a particular region and historical moment, was paradigmatic because it animated a series of questions about the proper 'object' of study for queer anthropology.

Are two same-sex persons who regularly engage in same-sex genital contact 'homosexual' by definition (and, by whose definition)? Or to pose the question in a more philosophical mode, are these practices necessarily 'sexual' or are they instead dependent upon the meaning given to eroticism, sexuality, and sexual subjectivity in any given case and context? Should a queer anthropology center attention on the lives of those who explicitly define themselves as 'lesbian,' 'gay,' 'queer,' or some other sexually inflected term of identity? Or should the subfield 'queerly' analyze the many social dynamics with which human beings engage? These kinds of theoretical propositions are ongoing debates within the field, and, I would argue, are not necessarily meant to be resolved. Rather these are opportunities to test and reset the boundaries of queerness, homosexuality, and sexual and gendered subjectivity. This is also precisely what queer anthropology has been adept at doing. Rather than providing comforting answers, queer anthropology has been far more interested in probing assumptions. In good deconstructionist form, it has been, and continues to be, an exercise in principled interrogations of sexuality as it is manifested in social relationships, identifications, affective practices, and political propositions.

Sexuality in the Field: Reflexivities and Methodologies

The designation 'queer anthropology' has been a point of debate for good reason. Many of the early works that would now fall under the rubric of 'queer anthropology' were not originally conceptualized as queer at all. Instead, importance was placed on their specific attention to 'lesbian' and 'gay' issues. Kath Weston (1993) notes that it was not until the 1960s that the classic studies in gay and lesbian anthropology were published. Research on homosexuality or transgendering continued to be conditioned by 'fear of professional repercussions' and 'reticence on the part of ethnographers' (1993: p. 340) for the next several decades. Queer ethnography tended to follow an 'ethnocartographic' logic "looking for evidence of same-sex sexuality and gendered ambiguity in 'other' societies" (Weston, 1993: p. 341). *The Many Faces of Homosexuality* (Blackwood, 1986), for example, featured essays on same-sex practices and identifications in a variety of national contexts. However, the volume marked an important advance since, unlike many academic disciplines analyzing sexuality, anthropologists were willing to cross borders and depart from the 'west.'

Institutionally, queer anthropology was also becoming established. In the 1970s, a handful of pioneering anthropologists founded ARGOH (The Anthropology Research Group on Homosexuality) within the American Anthropological Association in order to encourage research on gay and lesbian communities and to condemn (what was called at the time) 'homoerotophobia.' Membership expanded in the late 1980s and the organization changed its name to SOLGA (The Society of Lesbian and Gay Anthropologists). However, the nominal emphasis in the Society's title centered on the identity of the anthropologist him or herself, rather than on lesbian and gay subjects. Many, but not all, anthropologists researching sexual diversity identified themselves as lesbian, gay, or queer. While some forms of nonheteronormative sexuality that anthropologists were encountering across the world could be categorized as 'lesbian' or 'gay,' many others were not identity-based, or combined autochthonous forms of same-sex erotics with globally disseminated terms (Blackwood, 2010; Boellstorff, 2005; Howe, 2013; Sinnott, 2004). For the emerging field, it was critically important to designate an intellectual space for

(specifically) lesbian and gay anthropology. At the same time, it was clear from the outset that the categories of gay and lesbian could not fully describe transnational sexual identities, erotic experiences, or naming practices.

The 'queer turn' of the early 1990s in the humanities and social sciences was an auspicious intellectual shift for queer anthropology. Inspired in great part by Foucault's *History of Sexuality* and soon after, among others, Judith Butler's *Gender Trouble*, Michael Warner's *Fear of a Queer Planet*, Eve Sedgwick's *Epistemology of the Closet*, Gloria Anzaldúa's work on race, nation, and sexuality and Gayle Rubin's (Rubin, 2012) analyses of sex/gender systems, the development of queer theory was a rather epochal event. As a capacious umbrella category of belonging, queerness became a designation for many 'alternative' configurations of sexuality, gender, and desire. Yet, 'queer' was not without its problems. The term was originally derogatory, an insult that held a certain amount of venom in later iterations as it was appropriated as a term of empowerment and political progressiveness through organizations such as Queer Nation. Second, the concept was patently northern in origin (as an English language word). As it began to be applied in non-western settings, 'queerness,' whether in its subjective form or its theoretical life, still carried 'baggage' as a concept that was invented and reworked largely in the global north. Anthropologists, unsurprisingly given their methodological and theoretical orientation toward relativism, were cautious of projects that would erase cultural and social particularities, which 'queer,' nominally, seemed to risk.

The transition from lesbian and gay anthropology to queer anthropology was not without contention as scholars weighed the political, analytical, and categorical values of refashioning the field as a specifically queer anthropology (Boellstorff, 2007). In 2010, SOLGA was officially retitled as AQA (the Association for Queer Anthropology), thus claiming a queer designation while also removing the emphasis on the anthropologist's identity. These reflexive deliberations within queer anthropology also found themselves replayed in important methodological engagements. In *Out in the Field: Reflections of Lesbian and Gay Anthropologists* (Lewin and Leap, 1996), for example, ethnographers describe the contingencies of negotiating one's sexuality in the context of field research. In some cases, being marked as sexually 'other' is a liability and a struggle, and in other cases it is an advantage. Discussions of how sexual identity helps or hinders the research process raised broader concerns about how sexuality has (undoubtedly, always) conditioned the subjectivity of field researchers as well as how they are interpreted by their interlocutors. Lewin and Leap's collection posed the larger question of how sexuality and sexual identifications are managed in professional settings. The methodological paradigms of queer anthropology have simultaneously asked, in reflective and reflexive ways, how sexuality marks the field and how anthropologists themselves are marked by their sexuality.

Kinship, Sociality, and Queering Community

While anthropology may have always been a little bit queer, it is also true that queer anthropology has often tried to be concertedly 'anthropological.' Kinship, for example, one of the classic anthropological objects of inquiry, has been an important initial, and continuing, engagement for queer anthropology. In *Families We Choose* (1991), Kath Weston delineated the ways in which lesbian and gay families in the San Francisco Bay Area established family networks that were not predicated on biological or 'blood' relations, but rather on networks, connectivities, and shared values. Weston's interpretation of queer kinship practices offered a counterpoint to the dominant, prevailing thesis that American kinship was (necessarily) bound by rules of consanguine relationality. Ellen Lewin's work on lesbian and gay commitment ceremonies (1998) and lesbian motherhood (1993) illustrated both divergences and congruencies between queer experiences and normative practices of reproduction, kinship, and sexual identity in the United States. Comparing lesbian mothers and divorced heterosexual mothers in the United States, beginning in the late 1970s, Lewin found parallels between lesbian women's coming out experiences and straight women's divorces: each established greater autonomy. Being a mother, in both cases, emerged as a central identity and basis for relationships, illustrating how kinship profoundly determines social value, even, or perhaps especially, in the context of queer communities.

Queer kinship studies were at the forefront of a broader conversation regarding rather dramatic changes in family forms brought about by technology, globalization, and new opportunities for parenting and partnership. Echoes of these changes continue to resound as a new generation of queer anthropologists embark on the legal and cultural dimensions of same-sex marriage in the United States, especially as same-sex partnerships are, increasingly, becoming legally codified and receiving increased public support. Queer parenting practices also continue to be an important area of research, exploring, for example, how gay men conceive of their roles as co-fathers (Lewin, 2009). The next challenge for queer kinship studies will be to move discussion beyond the United States and Europe where it has largely focused and to extend analyses of queer parenting and partnerships to other regions of the world that have been conditioned by different histories and where we might expect very different futures. Discussions about queer kinship, family formation, and generational commitments are elements of a broader context that includes queer sociality and community formation, each of which has been a mainstay for queer anthropology.

Sexual identity has often served as a basis for solidarity and a shared sense of identification. However, because homoerotic desire and sexual orientation do not always, or in all places, translate into a collective logic, queer anthropology has sought to distinguish how sexuality operates in conjunction with other elements of social belonging. Mary L. Gray's *Out in the Country* (2009), for instance, demonstrated how queer youth in rural Kentucky have appropriated public spaces (such as high schools), neoliberal private institutions (such as Walmart), and social media spaces on line, to establish rural queer visibility. Gray's focus on rural queer populations shifted the optic of queer visibility from its usual locale in the urban metropole and illustrated important differences about queer lives beyond the 'meteronormative' focus of many queer studies. In the *Spaces between Us: Queer Settler Colonialism and*

Indigenous Decolonization (Morgenson, 2011), Scott-Morgenson illustrates how Native American sovereignty articulates with queer sociality, showing how white settler colonialism has been a primary condition for the development of modern queer politics in the United States. In *The Empire of Love* (2006), Elizabeth Povinelli contrasted indigenous communities in Northern Australia and a progressive, queer, radical fairy contingent to focus attention on what she calls 'social intimacy,' rather than identity. Her analysis, among others, signals a move within queer anthropology (and in queer theory more broadly) to examine postidentity paradigms. Moving the 'post' yet further is anthropological work that extends the category of queerness to include non-normative sexual practices that may or may not be same-sex or same-gendered. In *Techniques of Pleasure: BDSM and the Circuits of Sexuality*, Margot Weiss (2011) demonstrates how consumerism, notions of self-mastery, and strict regulatory regimes of behavior all operate to constitute a collective ethos among bondage, domination and submission (BDSM) communities. In this work and others, queer anthropology is not solely defined by same-sex sexuality, but rather more expansively. Here, queer anthropology echoes queer and postcolonial theories which suggest that dominant discourses are always embedded in, putatively counterhegemonic communities. Radically different forms of sociality are possible, but normative values are not easily sloughed off. Ultimately, subjectivity is not singularly aroused through sexual orientation, erotic behaviors, or affective desires, but instead defined by multiple, intersecting factors including gender, race, socioeconomic status, (post)-colonial conditions, and geolocation.

Performance and Performativity: Language and Gender

The relationship between genders and sexual behavior, as well as the values associated with both, has been a pivotal debate in the field of queer anthropology. Early on, Gayle Rubin articulated partial economic and feminist concerns, establishing a key theoretical device for sexuality studies including queer theory itself. In 'Thinking Sex,' Rubin described how some sexual acts are negatively marked as unnatural while others remain in what she called the 'charmed circle' of sexual behavior; that is, those that are at least nominally qualified by reproductive, marital, or romantic purposes. Sex/gender systems, as well as their origins and effects, would prove to be a critical domain for queer anthropological analysis. *Two-Spirit People: Native American Gender Identity, Sexuality, and Spirituality*, for example (1997), challenged the ways in which non-normative gendered behaviors have been, at times, mistakenly attributed as gay or lesbian identification. Through the voices of Native American two-spirit people themselves, the book uncovers the intimacies of these misapprehensions (including on the part of anthropologists) and in turn, further complicates questions surrounding the definitional boundaries of gendered and sexual being. Anthropological work in South Asia has demonstrated similar negotiations. Ethnographies centered on the lives of *hijras*, whom Serena Nanda (1998) called 'neither man nor woman,' have provided regional and historical lineages to practices of gender and sexual diversity. As Gayatri Reddy (2005) found, the third gendered lives of *hijras* are also shaped by spiritual commitments that provide an important point of definition for *hijra* subjectivity.

Queer anthropology has also grown through its engagements with the performative elements of gender and sexuality, as Rosalind Morris detailed in her review essay, 'All Made Up: Performance Theory and the New Anthropology of Sex and Gender' (1995). Esther Newton's *Mother Camp* (1979) was an early example of how sexual subcultures of camp and drag reproduced forms of inclusion through performances, ritualized over time. Later, Newton would revisit drag in her study of Cherry Grove (1993) a long time lesbian and gay enclave. Employing a historical perspective on the region's development, Newton also underscored how dimensions of class and gender functioned to establish status differentials between men and women. The fascination with drag, for Newton as for many queer theorists, has centered on how it re-performs gender bending and in turn, works as a deconstructive exercise of gender norms. Drag is a relatively small gesture that reveals worlds about the values surrounding gender systems. The iterative qualities of gender performance have been important to queer anthropological texts seeking to illuminate how individuals and collectives make, and make sense of, their social location.

Many gendered and sexed practices cannot be easily categorized as feminine/masculine, female/male, or homosexual/heterosexual. Whether under the mantle of 'trans' (-gender, -sexual, -vestism), or 'third' (or fourth) gender, these embodied and socially situated experiences have been an important area of research for queer anthropology. Don Kulick's (1998) vivid ethnography details the lives of Brazilian *travestis* – biological men who dress in feminine clothing, some of whom have taken radical steps to make their bodies more *feminino*. Injecting industrial silicon or motor oil to create the appearance of hips, breasts, and larger buttocks (or *bundas*), *travestis* who make their living through sex work often see these steps as a way to garner better pay. But more important is how these exercises in embodiment signal a greater desire to be, as Kulick puts it, 'not men.' David Valentine's *Imagining Transgender: An Ethnography of a Category* (2007) provides a close interpretation of the remarkably rapid rise of the category of 'transgender' in the United States, fomented through a series of academic engagements and political projects. The burgeoning field of transgender studies has an early precedent in queer anthropology. There are multiple examples of gendering practices in distinct regions of the world, such as fa'afafines in the South Pacific or women's masculinities in Asia, Africa, and Latin America (Wieringa et al., 2007; Blackwood and Wieringa, 1999). Queer ethnographic work on transgendering, has posed a series of theoretical challenges and generative discussions about how sexuality and gender become articulated and in turn, how anthropologists and others can do representative justice to them.

The ways in which gender and sexuality cohabitate, both intellectually and experientially, have been foundational to queer anthropology. In a parallel way, gender performance and the performativity of language have been central to debates in sociolinguistic queer anthropology (Kulick, 2000). Queer

theory drew very dramatic attention to the concept of linguistic and gender performativity. Following the linguist J.L. Austin, Judith Butler argued for example, that illocutionary acts of 'hailing' a sexual subject performs the act it is said to represent. In other words, to call someone 'gay' is not a descriptive exercise but a constitutional/determinative one that, repeated over time, comes to be accepted as a putative truth. How naming acts are performed and understood and how sexual categories are applied, appropriated, or retooled in queer worlds continues to be a dynamic domain for critical queer inquiry. While language use within queer communities had been analyzed in a folkloric mode cataloging lexical items, in *Word's Out: Gay Men's English* William Leap (1996) argued for a more sociodynamic approach that highlighted how gay men negotiated risk, cooperation, and coming out through specific linguistic forms and performances. Using life stories and interviews as well as gay magazines and books, Leap's ethnography foreshadowed later interventions in queer anthropology that would focus on gay pornography as cultural texts. The edited collection, *Speaking in Queer Tongues: Globalization and Gay Language* (Leap and Boellstorff, 2003), further transnationalized the analysis of queer idioms and speech acts, illustrating how global discursive flows and travel have influenced gay and lesbian lexicons and transformed the content of queer language systems.

Transnationalities and New Sexual Subjectivities

While queer anthropology can be traced to historical moments in the anthropological canon, queer anthropology has unmistakably burgeoned in the more recent era of globalization. In what they called a more generalized 'transnational turn' in lesbian, gay, and queer studies, the anthropologist Elizabeth Povinelli and the historian George Chauncey (1999), signaled how neoliberal globalization was being played out within the intimate domains of sexual subjectivity. For queer anthropology and the discipline of anthropology more generally, processes of globalization – including the flow of goods, ideologies, financial instruments, and human beings themselves – were not entirely new terrain. However, with the acceleration of these flows and their interrealtionships with putatively private domains, sexuality was becoming a more explicit, expanded, and vitally important area of queer anthropological research. Earlier works, such as *De Los Otros* (Carrier, 1995), *Latin American Homosexualities* (Murray, 1995), and *Islamic Homosexualities* (Murray and Roscoe, 1997), for example, outlined what can be glossed as 'indigenous' 'traditional' 'autochthonous,' or 'historical' modes of same-sex practices. Using the idiom of sexual models, these projects differentiated gender role-based behaviors (transgenderal), age-distinguished sexual practices (transgenerational), and reciprocal sexual behavior (egalitarian). Emphasis was also placed on how social stigma was apportioned according to one's 'role' in sexual acts, or how sexual shame was distributed. Roger Lancaster (1992) argued, for instance, that gender and sexual values in Nicaragua, historically, had allowed for a degree of low-status social recognition for *cochones* (loosely, 'fags'). A masculine man could, in this pattern of transgenderal sexuality, have sex with another man, as long as he maintained the 'active,' 'insertive,' and 'manly' role in the encounter. Similar sexual status hierarchies were, and continue to be, familiar in Mediterranean and Middle Eastern settings, among others. However, 'role-based' approaches have found significant critique in queer anthropology, and many have argued that sexual desire and erotic practices are far more diverse and malleable than role-based models would suggest. In the age of globalization, this criticism has found even more traction. It is not that sexual models or role-based practices have disappeared entirely, but sexual practices and the social values underlying them are increasingly intertwined with globalized forms of intimacy and epistemologies of identity.

The transnational turn in sexuality studies, and its continued relevance in queer anthropology, has demonstrated how erotiscapes around the world are changing as populations and queer communities come into greater and more regular contact with one another, either virtually or *in vivo*. As with all things regarding globalization, it is impossible to disregard the multiplicity of forces at work, including increases in commerce, trade, and tourism, as well as the emergence of new sexual subjectivities. In *Beneath the Equator* (1999), Richard Parker demonstrated how 'cruising' and sex work coincided in Brazilian urban space to engender gay men's communities. Parker's ethnographic material also raised the issue of HIV/AIDS and the dynamics of transitional health management (and failures), an area of research that has continued to be an important emphasis within queer anthropology. Analyzing the dynamics of sexual commerce and tourism in the Caribbean (2007), Mark Padilla has shown how gender and sexual behaviors have been transformed as nominally 'straight' men engage in sex with foreign (male) travelers while continuing to maintain heterosexual relationships with their female partners. In addition to transforming labor, gender roles, and sexual behavior, Padilla notes how the transnational flow of tourism and sexual commerce has created new challenges for HIV prevention and public health management.

As the insistence of globalization has increased, sexual subjects everywhere are being conditioned by a greater diversity of discourses and possibilities for imagining the sexual self. The dissemination of global media, internet communications, travel, and capital flows have also produced worries about how sexual difference may be subsumed under a monological 'global gay' sexual citizen. Because of its longstanding commitment to investigating how ideals and practices of sexuality travel, queer anthropology is well equipped for these moments of transnational erotic transformations. Even as sexuality – as a concept, a category, a practice – is in motion, this does not necessarily portend the wholesale erasure of non-western (or non-northern) forms of sexual identification or practice. Martin Manalansan's (2003) work in New York City, for example, describes how queer Filipino immigrants have created new modes of sociality in a diasporic context. They have retained certain cultural forms from their homeland, responded to new challenges in their diasporic home, and found ways to mobilize and articulate sexual sensibilities that eschew a strict distinction between (putatively) 'traditional' or 'modern' forms of sexual practice. Indeed, disrupting this developmentalist logic of sexuality, one that begins in 'indigenous' forms of same-sex sexuality and ends in

so-called egalitarian, 'modern,' or global models of sexual subjectivity, has been a central argument in transnational queer anthropology. Following the quotidian experiences of gay Indonesian men in the world's largest Muslim country – and examining how their sexual subjectivity has been informed by mass media, nationalism, and globalization – Tom Boellstorff (2005) has suggested that his interlocutors' experiences reveal 'archipelagic' contrasts and philosophical questions about what constitutes sameness and difference. Engaging with ongoing anthropological debates about nation states, Boellstorff argues that the cohering logic of the Indonesian nation state allowed for the formation of particular kinds of queer subjectivities. In addition to charting how global discourses and transnational diasporas shape and define sexual subjectivities, these sorts of studies challenge assumptions about assimilation more broadly. They demonstrate how immigrant practices and globally disseminated models of identity are being taken up and refashioned in global contexts.

Understanding how queer communities and individuals reconceptualize and rearticulate seemingly hegemonic global gay identities has been a critical emphasis in transnational queer anthropology. Evelyn Blackwood's (2010) work in Indonesia among the Minangkabau, for instance, has shown how same-sex loving women have adopted and adapted local, regional, and transnational forms of queer subjectivity. Megan Sinnott's (2004) fieldwork in Thailand also illustrates how women's same-sex sexuality has been negotiated over time and in particular gendered contexts. These studies, among others, have provided an important counterbalance to the gender disparity that has been the legacy of much of queer anthropology. Note that in essays that reviewed the state of the field of lesbian and gay anthropology in 1993 (Newton, 1993) and again in 2007 (Boellstorff, 2007), authors drew attention to the paucity of anthropological work on women's same-sex sexuality and affective relationships. Unfortunately, this is still true as men's sexuality continues to dominate the field. However, it is also true that women (as lesbians, or by some other moniker) have become a more robust subject in queer ethnographic studies, from social movements to shifting subjectivities (Dave, 2012; Howe, 2013; Wekker, 2006). This is a promising sign suggesting that the subfield's androcentric bias is being recalibrated. Scholarship on women's masculinities, transgender subjectivity, and the articulations between sexuality and feminism should continue to be a generative arena for future queer anthropological work.

Futures and Post-Queering Anthropology

Maybe it is unwise to prognosticate the future of any academic field but we do have precedent and patterns to discern our way forward, and queer anthropology has many vibrant prospects on the horizon. Continuing in the mode of transnational inquiry, the subfield will undoubtedly generate more accounts of queer lives around the world, bringing them into conversation with other elements of the socioscape including changing economic conditions and epistemologies of rights and relationalities between, among, and beyond queer communities. Many queer ethnographic works have been situated in the global north (especially the United States); other areas of the world, though to a lesser degree, have also been represented in queer anthropology (Latin America, the Caribbean, South Asia, Southeast Asia, East Asia, and Melanesia). However, more work is clearly needed in the Middle East and North Africa, as well as East and West Africa. While some queer anthropological work has been carried out in these regions (Gaudio, 2009), several are in the ethnocartographic mode (Murray and Roscoe, 1997) or only focused on queer sexuality in an ancillary way (Borneman, 2007), meaning that a significant gap remains.

The dynamics of communication, particularly in the era of global media, social networks, and online life, will undoubtedly continue to be of interest to queer anthropology. Anthropological work on new media forms has demonstrated how queer subjectivity can be created and contextualized in digital forums (Boellstorff et al., 2003; Gray, 2009; Herdt and Howe, 2007). Queer subjectivities that may be impossible elsewhere have found social space and new possibilities through the use of digital platforms and new media outlets. Future research will continue to complement social scientific analyses of media more broadly, including how media is produced, consumed, interpreted, and engaged. In the spirit of analyzing performance, performativity, and the impact of the Internet, queer anthropological studies of pornography also promise to generate provocative readings and interpretations of how queer bodies are rendered through cinematic tropes and circuits of consumption.

The next generation of studies in queer anthropology will continue to analyze the confluences of globality, (post)-identities, and shifting subjectivities and allegiances to nation, state, race, gender, and sexuality. Our current global episteme is one that circulates massive amounts of knowledge and information implicating political, social, and sexual selves. New queer anthropological work on transnational advocacy and ethnographies of activism (Howe, 2013) uncover how queer political agendas become formed in part through social movements and the ideologies that have preceded them as well as how they are conditioned by neoliberal or neosocialist contexts. These studies should continue to illustrate how queer activism also informs other movements for social justice and equity. Following earlier studies in the anthropology of emotion, the affective turn in the humanities and social sciences will likely continue to inform queer anthropology, demonstrating, for example, how emotive, affective practices condition political formations (Dave, 2012). The meaning of queer personhood and what constitutes equality are intellectual questions that are being answered, in part, through analyses of how human rights models become articulated with autochthonous juridical forms and social values. Sexual asylum claims, queer migration policies, transnational same-sex marriage, and hate crime legislation will continue to be critical areas of engagement going forward (Murray, 2014). In the domain of the anthropology of experts and expertise, queer anthropology will also likely continue to find productive sites of analysis that center on innovations in queer law and scientific treatments of queer biopolitics.

Michael Warner, one of queer theory's founders, has suggested that we are now entering a post-queer phase of scholarship, one that has shifted queer theory's abiding concerns to

new rubrics of inquiry including the deep inequalities of globalization, and a fascination with temporality, affect, and normative repudiations. For queer theory, as for its anthropological kindred, these turns in the queer imaginary are not divested from understanding how sexuality is maintained and transformed, but they are open to new contingencies and mediations. Whether post-queer-ness is upon us or not, we know that queer anthropology has proven itself agile in comprehending new theoretical and ethnographic coordinates. It has been an anthropological 'bent' with a heterogeneous and generous intellectual ontology that bodes well for future innovation.

Queer Geography

Abstract

Queer geographies overlap with the geographies of sexualities, but the two fields are not entirely interchangeable. Queer geographies offer an approach that combines queer theory with spatial analytics to describe and analyze the social coconstitution of sexuality and space. This article discusses the contributions of queer geographies to scholarship, focusing on three geographical lenses: scale, mobility, and place-making. The article first charts inter-relations of sexuality and space at the scales of the body, home, city, and nation-state, and then traces queer processes of emplacement and displacement ranging across the local, national, global, urban, and rural.

Introduction

The disciplinary label 'Queer Geography' maps out a wide field, the boundaries of which are somewhat indistinct and remain in dispute. In this article, we allow for these uncertain borders by offering, not so much a definitive cartography, but a journey of exploration. We outline here the emergence of sexuality as a concern in the discipline of geography, including the expanding influence of queer theory; suggest ways in which sexuality and space both constitute and are constituted by one another at a range of scales; note an increasing disciplinary interest in mobilities within, across, and through these scales; and explore the concept of place-making as it intersects with mobilities and queer sexual identities. We allow 'queer' two – admittedly contradictory – meanings here. Firstly, queer operates as a catch-all term for a range of 'alternative' sexual and gender minorities, including those who identify as lesbian, gay, bisexual, queer, and/or transsexual/transgender, as well as those who, while homosexually active, do not adopt an identity based on their sexual desires. Secondly, queer can be defined as a process which highlights fluidity and complexity and which specifically disrupts sexual and gender identity labels. By incorporating these two definitions, we are able to explore 'queer geography' as, firstly, an examination of intersections between sexuality and space as studied within the field of geographies of sexualities and, secondly, as its own distinct field which initially emerged from geographies of sexualities but which has since expanded to encompass a range of other concerns (Knopp, 2007).

It was in the 1970s and 1980s that homosexual identities emerged as a disciplinary concern for some geographers (Bell and Valentine, 1995). The primary interests of this early research were in mapping the location and development of the social, commercial, and residential urban spaces of gay men and, to a lesser extent, lesbians. Gradually, feminist geographers and Marxist economic geographers began to push lesbian and gay geography away from its initial positivist epistemologies and toward more radical explorations of power relations. Larry Knopp, for example, explored intersections between sexuality and the spatial dynamics of capitalism (Knopp, 1992). Into the 1990s, the influence of queer theory – drawing particularly on the work of Judith Butler – located performance and representation as critical factors in studies of sexuality and space. The 1995 publication of the edited volume *Mapping Desire* (Bell and Valentine, 1995) marked a significant moment for poststructuralist geographies of sexualities that sought to queer understandings of how sex and sexuality operate in and through space.

What such research achieved was a new visibility for the role of sexuality in how space is constituted, imagined, and experienced, and just as importantly, for the role of space in the development and construction of sexual identities and behaviors. Concentrating largely (but not exclusively) on the experiences of queer populations, the research considered how heterosexuality is often spatially constituted as normative, thus rendering nonheterosexual people out of place or as needing to queer space to both contest heterosexual norms and to create a sense of belonging. Space and sex were seen as intertwined and constitutive at a range of scales including the body, the urban and the nation; as intersecting with race, gender, and class; and as critical to a range of geographical disciplinary areas, most notably social and cultural geographies, but also economic, political, and health geographies.

Even though the field has been heavily influenced by queer theory since the 1990s, research within geographies of sexualities has more recently been critiqued by some queer geographers (or at least by geographers using queer theory) as overly concerned with identity politics and with the twin binaries of male/female and heterosexual/homosexual. Queer theory itself largely defies definition, seeking to maintain its radical potential by refusing to adhere to any fixed meaning. At its core, however, queer theory rejects sexual and gender binaries in favor of fluidity and complexity, finding sexual identity and its role in space not as fixed and constituted but iterative and mutable. To queer theorists, 'queer' is not an identity but a process; not a noun but a verb. In this light, queer geography can at times be seen to include geographies of sexualities, but the two should not be understood as interchangeable labels for the same field (Knopp, 2007). Queer geography, thus defined, seeks not to examine homosexual (or queer) space as the nonnormative 'other' to the normative of heterosexual space, but instead urges a queer approach to space which rejects any such binary (Oswin, 2008). Unlocked from a binary view it is possible to see, for example, how materialized performances of

homosexuality may in fact enforce normativity, and/or to locate in space nonnormative performances of heterosexuality.

Scale

Both geographies of sexualities and queer geographies frequently examine the spatial operation or constitution of sexuality using scale as a conceptual and methodological framework. For those not familiar with the concept, scale is a quintessential focus of geographical thinking that refers to the size and scope of the 'space' under examination, as well as the relationships between scales (e.g., hierarchical, networked, etc.). In disciplinary debate, the notion of scale is increasingly complex. If once presented as a fixed set of analytical categories, often arranged in a fairly rigid hierarchy from smaller to larger (e.g., body, urban, regional, national, global), these geographical scales have themselves come to be understood as socially constructed, negotiated, and reproduced. Sexuality often plays an important role in this construction across various scales from, for example, the body to the home, the community, the city, the rural, the nation, and the globe. Below, we take four of these scales as examples of how geographers have investigated intersections between sex, sexuality, and space.

The Body

According to Johnston and Longhurst, the body is the "primary space in which and around which we construct our subjectivities" (Johnston and Longhurst, 2010: p. 39). Our bodies operate both *as* space and *in* space and determine ways in which we are included or excluded; experience regulatory approval or disapproval; are materialized as sexualized and gendered beings; and physically or metaphorically move within and through space. The body is a site in and at which we construct our sexual identities and through which we perform those identities. It is also a heavily monitored space which is subject to the same socially constructed discursive regulation as wider scales, and thus has become a significant site of interest for geographers seeking to understand the spatial aspects of sex, gender, and sexuality.

One indicative element of sexuality at this scale is the metaphor of the closet (Brown, 2000). Homosexual people are frequently described as being *in* or *out* of the closet according to whether they are attempting to hide or determined to reveal their (homo)sexual identity. This is an explicitly spatial metaphor in which the body is materialized as a site of identity performance. Along with this spatial metaphor, Michael Brown has shown how gay men at times describe the closet as a 'real' physical or material space and as a "way their physical geographies are demarcated" (Brown, 2000: p. 48). Migration from a town, city, or nation considered homophobic (and in which one's sexuality must be kept private) to a location in which homosexuality is more widely accepted (and in which a gay identity can be publicly performed) can therefore be seen as both a migration across wider scales and also as a move from *in* to *out* of the closet at the scale of the body (Gorman-Murray, 2007).

Geographers have also examined how the sexual and gendered body is operated upon by regulatory forces. This research draws on the work of Foucault, who has argued for the powerful, historically, and geographically constituted role of discourse in shaping and controlling sexuality from the individual body to the nation. Displays of physical affection are frequently cited as examples of how, through social regulation, the heterosexual body and the homosexual body experience space differently. While a public kiss between a heterosexual couple may go unnoticed or uncommented on, a kiss between a homosexual couple may well elicit comment, abuse, or even violence. Such regulation delineates sexual identity performance according to a public/private binary, denying or troubling access to, or safety in public space for nonheterosexual people (Johnston and Longhurst, 2010).

Similarly, the gendered body is regulated according to a male/female binary, leaving intersex, trans, or ambiguous bodies out of place and subject to the possibility of censure or attack (Doan, 2007). The normative body is delineated as clearly and publicly either male or female. By conforming to this binary through the space of the body – for example, by wearing clothing deemed 'appropriate' to our gender and comporting ourselves according to masculine or feminine expectations – we may ease the process of our participation in public space. Bodies which refuse or are unable to conform in this way may well find their access to space limited or uncertain, and potentially dangerous.

The Home

The public/private binary can also be queried, queered, and deconstructed at the scale of 'the home,' which is often synonymous with 'private space' or the 'private sphere.' The space of the home is often thought of as a refuge or sanctuary from the public sphere. We go home to relax and be ourselves. In terms of sexuality, this may mean that the home is a safe space for the development and performance of sexual or gender identities, away from the prying eyes of regulatory forces. The research of a number of geographers has found, however, that the home is a complex space imbued with a variety of (at times conflicting) meanings and in which intersecting categories of sexuality, gender, race, ethnicity, age, and class continue to hold influence.

The public/private binary, which would at first appear to exclude the outside world from the sanctity of the home, has been found to be unstable and unclear (Gorman-Murray, 2012). The monitoring and regulation that structures performances of sexuality and gender in public may equally find its way into the home through several possible avenues (while some ostensibly public spaces can also become 'private' at certain times or through particular uses – e.g., public toilet stalls).

For instance, home is often thought of as a space of family, generally imagined and structured as a heterosexual, monogamous couple raising children (Johnston and Longhurst, 2010). Geographers of sexualities have complicated and expanded this imagining by investigating the ways in which nonheterosexual individuals, couples, and families make or experience home. How, for example, do the experiences of lesbian or gay family members living with heterosexual parents complicate both the notion of home as a place for heterosexual families and/or as a place of safe gay or lesbian identity performance? (Valentine et al., 2003). For queer teenagers or young adults, the home

may in fact be a form of closet, in which they must hide or mask their sexual identities for fear of negative repercussions from heterosexual family. Under such circumstances, public spaces such as bars or nightclubs may at times offer a safer venue for identity development and performance than the home, and indeed, can become home*like* (Gorman-Murray, 2006), revealing that public/private permeability flows both ways.

Andrew Gorman-Murray has found that home can also act as a space for a queer politics of identity (Gorman-Murray, 2012). In configuring home as a space from which a homophobic world is excluded, gay men may carefully monitor public intrusions and attempt to enforce a division between the public and the private. Equally, however, some gay men were found by Gorman-Murray to exploit the ambiguity of the public/private binary in order to enact a political identity. The flying of a rainbow flag (a symbol of the gay pride movement), for example, is a public performance of sexual identity enacted in or at the scale of the home. This is a specifically political act, defying attempts to exclude gay men from the public sphere by placing the sexual make-up of a private home on public view.

Further complicating the idea of home as a space of safety and security is the fact that, particularly for women and children, home may be a site of abuse and danger (Johnston and Longhurst, 2010). While public space is often presented as the dangerous sexual other from which home can provide sanctuary, such an imagining elides experiences of family violence and sexual abuse in the home. By making such experiences visible, queer geographies reveal how fixed notions of sexualized space, as well as set binaries of public/private or safe/unsafe, mask the ways in which spaces like the home remain iterative, unstable, and uncertain.

The City

In terms of geographies of sexualities, 'the city' is perhaps the scale at which the most substantial amount of work has been conducted over the longest time period (Brown and Knopp, 2003). As noted above, it was the urban spaces adopted by visible gay and lesbian communities that first prompted a geographical interest in sexuality in the 1970s and 1980s. Since that time, the field has expanded to investigate the role of urban space in the development of a more diverse range of sexual and gender identities (including heterosexuality), as well as to consider intersections between sexuality and race, age, ethnicity, ability, gender, and class.

Across that time period, gay men and lesbians in many of the large cities of the Western world have experienced radical changes in public acceptance, legislative reform, and access to urban space. While these changes arguably reflect a growing level of social equality for nonheterosexual individuals and a growing ability to create or produce queer urban spaces, queer geographers have examined ways in which sex and gender continue to be regulated and in which the production of queer urban space may in fact produce inequalities and enforce normativity.

Petra Doan, for example, has examined the gendered nature of queer urban spaces, highlighting a potential lack of tolerance for transgender or gender variant people (Doan, 2007). While noting that transgendered individuals do report feeling safer in visibly queer areas than in cities without a queer space, Doan also finds that lesbian and gay residential or commercial areas "replicate a strongly heteronormative gender dichotomy" (Doan, 2007: p. 70). Thus, sexuality can in fact intersect with gender to produce normativities that would at first seem out of place in a queer space.

Intersections between sexuality, race, and class may similarly trouble the place of queer individuals in some queer urban spaces. Berlant and Warner, for example, note attempts by local property owners to exclude 'queer pilgrims' – frequently young, African-American people – from making use of gay neighborhoods in New York City (Berlant and Warner, 1998: p. 563). To Berlant and Warner, access to such spaces should not be predicated on the ability to buy into an expensive property market. Visitors play an important role in the production of queer urban space while intersections of class, race, and sexuality may produce normativities which exclude those visitors.

The Nation-State

Geographers have also examined complex constitutive interactions between sexuality and the nation-state. Perhaps the clearest example of how the nation constitutes the experience of sexuality for its queer citizens is the legal regulation of homosexual sex acts (Binnie, 2004). While, for example, sex between consenting male adults was decriminalized in Great Britain in 1967, nation-states including Indonesia, Iran, and Malaysia maintain strict bans (ILGA, 2013). The ability to perform (both in public and private) and to develop a (homo)sexual identity is thus heavily constituted by the state. Even in those nations which have decriminalized homosexual acts, the state continues to play a role in deciding which kinds of sexual activity are 'moral' or acceptable (e.g., monogamous relationships) and which are not (e.g., public sex, sadomasochistic (S&M) sex). Sexual subjectivities are thereby specifically constituted at the scale of the nation-state, while sexual identities and behaviors demarcate and limit the boundaries of citizenship.

It is also true, however, that sexuality plays a significant role in how a nation will imagine itself into being. In part, this may be enacted through attempts to exclude nonheterosexual identities from the national imagination. Recent legislation in Russia, for example, has banned the holding of gay pride parades and the distribution of lesbian, gay, bisexual, and transsexual or transgendered (LGBT) information to children (Associated Press, 2013). Gordon Waitt has shown that it is possible for sexuality to intersect with and disrupt national mythologies in a way that (even if only temporarily) queers those mythologies (Waitt, 2005). Waitt explores the centrality of sport to Australian nationalist imaginary and notes that the Gay Games sporting festival in Sydney in 2002 provided, for some participants, a sense of queering the presumptive heterosexuality of the Australian sportsperson's body.

In many ways, the aims of lesbian and gay activism can be seen as efforts to gain inclusion for nonheterosexual people as full national citizens. For many queer individuals, there remains a significant tension, however, between the desire for inclusion within the nation-state (and acquisition of the benefits of full citizenship) and a feeling that such inclusion is predicated on participation in a consumerist system which demands conformity and elides difference. As Waitt notes,

some in Sydney felt that participation in the Gay Games signified less a queering of the sporting body as it did a conformist acceptance of nationalist normativities. The predominance of military service and same-sex marriage as aims for lesbian and gay activism in the United States (and other countries) also signify this tension (Binnie, 2004). While some argue that participation in the military and access to marriage signify a queering of these institutions and of the nation-state by which they are regulated, others see instead the dequeering of communities now conforming to the dominant (hetero)normative values of the state.

These examples of scale are by no means conclusive, but are instead offered as examples of how geographers (and others concerned with sex, sexuality, and space) have theorized and examined the spatial aspects of sexuality. If geographers have taken a specific interest in connections between sex, sexuality, and space at various scales, it is also true that an increasing focus has been applied to movement within, between, and through scales, and the relations between movement and place-making. Below, we explore some examples of research into how sexuality impacts on entwined processes of mobility and place-making across scale and space.

Mobility and Place-Making

Mobilities

Sex and sexuality can be seen as critically important inspirations for or limitations to mobility and migration. Queer geographies can offer valuable insights into mobility, for example, by investigating the role of sexuality in encouraging migration or in constituting the experience of movement across and within space. As argued by Nicola Mai and Russell King, "love, and sometimes alongside it, sex can play a decisive role in the imagination and enactment of the choice to migrate" (Mai and King, 2009: p. 296). Mobility itself can be enacted at and through different scales, with various terms applied to these movements. At a local, everyday level, we might think of such mobilities as commuting (to and from work) or 'cruising' (a form of everyday mobility perhaps quite resonant with gay male subcultures). At broader scales, both temporal and geographical, we can refer to ideas of migration, which might be intraregional, intracity, intranational, or international. We consider some of these scales of mobility in relation to sexuality and space below.

Taking the broadest scale and range of mobility, in terms of international migration, Mai and King note a "sexual turn" (Mai and King, 2009: p. 296) in migration studies which, heavily influenced by queer theory, has placed migrants (including migrant workers, refugees, and others) as sexual beings. Such a framing allows for emotional and sexual desires to be seen as central issues in why people migrate or how they experience the spaces from, to, and through which they move in the process of migration. This research has included, for example, study into the impacts of migration on the 'traditional' or established sexual and gender norms understood or practiced by migrant groups. Nader Ahmadi, for example, argues that among Muslim Iranian migrants in Sweden, "traditional authoritarian patriarchal sexual relationships are giving way to more egalitarian relationships" (Ahmadi, 2003: p. 702).

Mobilities and sexuality also significantly intersect in what Larry Knopp has called "queer quests for identity" (Knopp, 2004), which are often perceived and experienced at the intranational scale, although at various levels of displacement within the nation-state. These are the journeys taken, at a range of scales (within cities, between cities, between regions, etc.), by queer people seeking a space in which to develop and perform nonnormative sexual or gender identities. This may include, for example, gay men and lesbians who travel from their homophobic home-of-origin (be it a rural area, city, or nation) to a more accepting location in search of a safer space in which to come out as gay or lesbian. At a simplistic level, such a journey may mark out an almost cinematic narrative, in which our hero(ine) escapes from the dark closet of the rural, travels through a series of adventures and is left, in the last scene, finally free and forever out in the city. Away from the cinema screen, mobility for the queer pilgrim is more complex and may involve a series of journeys, returns, and an ongoing, iterative process of making and unmaking both place and identity (Gorman-Murray, 2007).

It is important to note that mobility does not only signify migration across wider scales such as rural to urban, city to city, or nation to nation. If we accept that sexuality is spatially constituted, then it is possible to see how queer people may adapt, (re)make, reveal, and hide their sexual identities in different ways when moving across smaller scales. A businessman who is out as gay at home but closeted when traveling on business, or a married man who only explores his bisexual identity online or in specific material spaces, suggest examples of how hybrid sexual subjectivities may be materialized differently as queer people move through space (Knopp and Brown, 2003). 'Cruising' is another classic example, in which gay men, bisexual men, or men-who-have-sex-with-men seek connections and/or sexual encounters with like others as they move through public urban spaces day-to-day, including streets, parks, train stations, and pubs. Cruising palpably links same-sex activities and subjectivities – both deliberate and furtive – to everyday urban mobilities such as walking, commuting, and driving. Queer mobilities – and the queerness of mobility – thus encompass banal or everyday processes as much as national or global displacement.

Place-Making

At first glance, the concept of place-making may seem to sit in contrast to – or perhaps be seen as the conclusion of – mobility. At the end of their travels, for example, migrants may appear to come to a rest and make a place of their own. Geographers have, however, examined place-making as intertwined and in constant interaction with mobility (Knopp, 2004; Gorman-Murray, 2007). As we have argued above, mobility indicates everyday movements as much as it does global migrations. Place-making is a process throughout our lives and, for that matter, throughout each day, as we move at the scale of the body, the nation, and the globe. Geographers of sexualities have examined the significance of sexual identity in the need and the desire both to move through space and to make place. Making a place for sex, for community, or for the construction and performance of an identity takes place at the scale of the body, the home, the neighborhood, the city, and beyond.

Below, we look at some examples of how place-making is performed by queer populations.

The gay neighborhood (or gay territory, gay ghetto, or 'gayborhood') is a frequently cited example of queer place-making, in which nonheterosexual urban populations have established – through commercial enterprises, community organizations, and residential spaces – a visible presence in a particular suburb or area of a city (Brown, in press). If once seen in negative terms as a kind of containment of homosexual populations as enforced by the mainstream, these spaces would eventually be understood in terms of a politics of identity, in which gay populations appropriated urban space as a means of gaining economic and political power as well as social protection. The place-making process here is in some ways depicted as an end-point of queer migrations, in which gay men are best able to be gay (or to adopt a particular form of gay identity) once they have made a place for themselves in the gay neighborhood of a large city.

Geographies of sexualities have often depicted this process of place-making as one in which a gay community reacts against the heteronormativity of urban spaces by queering a space of its own. This is never a fixed and final ownership of space, however, but is an ongoing and contested process which – while offering queer populations a level of safety and a feeling of belonging – may also enhance the dangers of being out and visible as queer. In some instances, therefore, gay men may prefer to make place in a way that masks or hides their sexual identities (Brown, 2000). This form of place-making, rather than queering space, may actually contribute to spatializing and reinforcing heterosexual normativities.

Although place-making in the gayborhood has often framed homosexual identities in terms of the urban, geographers have taken an increasing interest in how queer populations perform processes of place-making in rural areas (Gorman-Murray et al., 2013). Whether as transient moments or long-term migrations, investigations into queer rural place-making have the potential to both highlight the role of sexuality in the constitution of rural spaces and to examine how sexuality is constituted differently between the rural and the urban, while also drawing connections between these material and imaginative spaces.

In terms of transient or temporary rural place-making, geographers have, for example, looked at the meanings and impacts of annual womyn's (Browne, 2011) and gay, lesbian, bisexual, transsexual or transgendered, and queer (GLBTQ) (Gorman-Murray, 2009) festivals held in rural areas of the United States and Australia, respectively. Kath Browne notes ways in which womyn festival–goers seek out or attempt to create a rural utopia which specifically excludes men (and, more controversially, trans women). For the time of the festival, this creates a space for sexual exploration and frames the rural in terms of an escape from the heteronormative regulation of the city. Gorman-Murray contrasts the different meanings of a rural GLBTQ festival for rural residents and urban visitors, with the first viewing the event as a political assertion of their visibility and presence in rural spaces and the latter seeking a rural idyll which places rurality as an "aesthetic commodity for urban consumption" (Gorman-Murray, 2009: p. 81).

It is equally possible to contrast the experiences of lesbian and gay rural residents who were born in a rural area with those who have decided to migrate from the urban to the rural. Geographers have successfully disrupted fixed narratives which frame lesbian and gay migrations as escape from the oppressive rural and toward urban freedom by examining the place-making processes of this latter group. Lesbian separatist communities, for example, as well as gay male groups such as the radical faeries, have undertaken a form of rural place-making in which they seek freedom *from* the city, not freedom *in* the city. Rather than finding an urban space in which to come out as lesbian or gay, some instead seek out an escape from heteronormative (or homonormative) urban experiences and create a rural space for themselves in which to construct and perform a differently constituted form of homosexual identity.

Conclusion

The bourgeoning range of scholarship within queer geography demonstrates that the diverse facets of sex and sexuality – comprising social norms, institutions, and regulations, alongside bodily desires and pleasures – cannot be understood without an interrogation of the spaces, places, scales, and mobilities through which sexual lives, identities, behaviors, and relationships are constituted and practiced. Viewing the world through a queer geographical lens, it is possible to challenge the idea that the spaces in which we live and the sexual and gender identities we adopt are natural and fixed. Instead, we can see that socially constructed ideas of space and of sexuality (as well as gender, race, and class) are constantly in dialog and forever in a process of creation, regulation, and melting away. Sexuality constitutes and is constituted by space such that our experiences of, participation in, or movement through one is intrinsically tied to the other.

Queer Theory and Intersectionality

Abstract

This article uses theoretical insights to explore the future of queer theory as it engages with intersectionality in a manner that will lead to the development of a framework that articulates the complexities of the lives produced by intersections of gender, race, culture, identity, and sexuality. This direction involves exploring the nonnormative alignments of sexuality, resisting the tendency to essentialize identity or conflate it with mainstream definitions of gender and sexual expressions.

Introduction

Contemporary progressive political movements have often faced the problem of proving legitimacy and authority due to lack of representation or diversity. Activists have long taken issue with the politics of representation and the problem of who speaks for and about others. Much of the experience-based literature articulates a clear divide between a sexuality-based lesbian, gay, transgender, or queer cultural identity and resulting theories and ones that are based on race or ethnicity with the two paradigms rarely intersecting to form a comprehensive legitimate discourse. Intersectionality alone according to Butler and Scott (1992) does not produce good theory. Such a theoretical practice would not end confusion or ambiguity but would allow for attention to and critical analysis of inequalities. Intersectionality points to the fact that the work of intersectionality is more complex and contrary to anything that is theoretically imagined.

Academic interest in how intersectional discourse shapes racialized, gendered, sexualized, and oppositional subjectivities is often tied to academic attempts to shape intellectual commitment, which I would say is very much the case with my following exploration of queer theory and intersectionality. In the following discussion, I am using Shoats' (2002) line of analysis in terms of looking at relational maps of knowledge that highlight the negotiation of sexuality as it is presented and understood in diverse situations and context. I will also explore the future imaginings of a queer theory that engage intersectionality in a manner, which will lead to the development of a framework that enables one to articulate the complexities of the lives produced by interactions of gender, race, culture, identity, and sexuality.

Development of the Concepts

With the increased emergence of queer subjects within mainstream discourse and the elevated demands for political voice and representation has come a stronger strategic resistance to the mainstream tendency of cultural homogenization. Queer subjects or those whose sexual identity, orientation, or behavior is seen as oppositional to the heterosexual norm are counteracting dominant discourses and requiring from social work practitioners a significant change in methodological, political, and culturally based theoretical approaches. This shift would allow for the articulation of identity and the claiming of space in history, while creating a political platform in terms of rather than in spite of the dissention that marks queer subjects as different from the mainstream. Histories of queer cultures and communities are scarce, not only in a Western context, but also in a global one (Manalansan, 2003). Very little is known about same-sex practices or how same-sex desire is theorized. Even more unsettling is the limited attention paid to same-sex desire, sociopolitical location, and the conveniently constructed silences around the relations between and around sexual orientation, gender, race, identity, and subjectivity (Massad, 2007).

To fully understand and support a queer theoretical framework, readers need to move beyond the gaze of queer subjects as the history of a marginalized minority population and look at the organization of social locations, the resulting intersections, and the impact on queer subjects in the widest possible sense. This group ought to be considered as part of and as central to the historical analysis, which validates the Foucauldian concept of the production of sexualities (Foucault, 1990).

The current academic study of sexual orientation that has been connected to the emergence of queer politics of identity and queer theoretical formations has historically focused on Western examples, with primary emphasis placed on white, middle-class gay life (Berube, 2001). A review of the writings of racialized lesbians, gay men, and queers does not produce a critical mass or a coherent body of published works or authors. This is due in part to historically limited institutional access but more so to differing or competing priorities as well as divergent definitions and ways of addressing sexuality and queerness. Queer communities globally may very well express solidarity with each other, but in the day-to-day working out of collective liberation struggles what must be acknowledged is a twofold reality: a clear and active recognition of the extent and nature of the varying contexts and a rich and deeply reflective understanding of the contrasting priorities that these contexts create. Being a queerly marked subject entails the negotiation of identity, politics, and desire as one moves between cultures, regions, and nations. It involves answering to a plethora of terms depending on language and location. It further involves acting on emotions, feeling desire, and engaging in the sexual practices that have diverse meanings and

priorities depending on locality and situation. While other marginalized groups have been defined depending on location and historical and situational context, the current discussion strategically focuses on queer identity.

In the following discussion, I highlight that the failure to use an intersectional approach in the discussion of queer theory can lead to the dislocation of particular marginal identities and the dismantling of progressive coalition building (Coloma, 2006). A queer theoretical view that centralizes intersectionality, I believe, will inform and signify the dialogical relationship between categories of social location, historically specific categories of sexualized identities, and the assumptions of race and location in the lives of queer subjects.

The Unpacking of Queer Identity

According to Epstein (1994), sexual meanings are not universal absolutes but ambiguous and problematic categories, with this becoming more evident as sexuality and sexual meanings are explored globally. For example, I would argue that most forms of oppression are based on what a person is or what they are perceived to be, irrespective of what they do or how they live. Individuals are discriminated based on who they are, for example, being a woman, a Muslim, or a racialized subject. This oppression occurs not because of what that person does but because the individual does it in a marginalized body. In the case of queerness, I believe that it is less a matter of who or what they are that is considered offensive but rather what that person is perceived of sexually doing or not doing.

Queer subjects and their nonconforming sexual behavior have been historically persecuted by state-sanctioned legislation and resulting discrimination. For example, Canada's unreformed same-sex laws, like those of most former European colonies, were modeled after European sodomy statutes, which were developed to control same-sex practices deemed as endangering the nation-state. Religious antihomosexual ordinances were also a part of this construction of same-sex laws (Kinsman, 2001). These laws were in keeping with the imperial and colonial agenda of the day, which aimed to wipe out and exterminate any sexual practices in violation of heterosexual normativity and those who engaged in them (Epprecht, 1998). Despite the historical creation of global state-sanctioned homophobia, most Western countries have long since reformed these laws, but the damage is irreversible and far-reaching. These statutes have not only aided in the erasure of queer history, the elimination of queer subjects, and the silencing of narratives through fear and state-sanctioned violence, but also left societies with the mechanisms that enable the continued persecution of queer subjects, since many former colonies still practice British, French, and Roman Dutch law and since the moral doctrines of Christianity have replaced traditional indigenous values. This persecution is also extended to countries where Islam is dominant (Tamale, 2011).

The most recent example of how colonial law still applies to modern-day democracies can be seen in the decision of India's Supreme Court in December 2013, which took the world's largest democracy a step back when it decided to overturn the 2009 lower court ruling to decriminalize homosexual acts between consenting adults (Vasudevan, 2013). The original Indian Penal Code mirrors the language that can be found in the laws of all former European colonies: "punishment for activity against the order of nature…" This application of colonial law is also seen across the African continent. The number of constitutional articles regulating homosexuality varies, but the wording of the offense is virtually identical. For example, in Uganda, "any person who has carnal knowledge of any person against the order of nature is guilty of an offense and is liable to life imprisonment" and the Nigerian Penal Code states that "any person who has carnal knowledge of any person against the order of nature … is liable to imprisonment for 14 years" (Madi, 2005).

The concern is as previously stated not with who queers are but with what they do. In current political articulations of queer sexualities in the West, social and cultural norms have been reconceptualized and are standing on their own merit, even though definitions remain in my estimation, unstably defined and coded. In the Western context, the phrase 'lesbian and gay' has become the standard way of referring to what only a few years ago was simply gay and prior to that homosexual (de Lauretis, 1991). Queer politics, on the other hand, has come to replace older modes of lesbian and gay politics by coexisting alongside them while at the same time opening up new possibilities of sexual expression. Queer subjectivity creates a new space in the framework of sexuality. The concept of identity and identity politics becomes crucial in the understanding of the functioning of queer theory.

Queer is said to transcend difference, to be gay or lesbian is merely to be assigned an identity, and to be queer requires the visioning and production of abstract genderless free agents who are definitionally indeterminate (Warner, 1991). Queer theory, then, attempts to unpack the identities 'lesbian' and 'gay,' and subsequently demonstrate how these categories are overdetermined by factors such as heteronormativity, race, gender, and ethnicity (Martinez, 2003). Queer theory thoroughly investigates sexuality by exploring themes of history, marginalization, exclusion, normalcy, social location, and political agency, all of which are crucial in the investigation of lives that stand outside any dominant culture.

Primarily concerned with documenting past and current manifestations and implications of same-sex attractions, queer theory operates from the perspective that heterosexuality or normative sexuality could not exist without queer or anti-normative sexualities. What, then, are the discursive constructions and constructed silences around the relations of race to identity and subjectivity in the practice of same-sex desire within the development of intersectional queer subjectivity? How do sexualized identities shaped by silence coexist with other sexualities that have not experienced historical erasure? How do these subjects articulate the discourse that so forcefully shapes their lives?

The Tale of Two Theories

The introduction of the term 'queer theory' by Theresa de Lauretis in 1991 aimed to encompass new histories of gays and lesbians (Goldman, 1996). In 1989, Crenshaw had introduced the term 'intersectionality,' which set out to amplify the systematic ways in which differences in social location such as,

but not limited to, race, gender, sexuality, and socioeconomic status were interrelated as distinct categories rather than conflated into a single experience of oppression. Difference was seen by both queer and intersectionality theories as central to the understanding of how marginalization was experienced and lived. Queer theory was seen as having the ability to problematize what it meant to be and live as a lesbian or gay person. Queer theory was also seen as the vehicle of desirous utopian imagination, as in the style of Warner (1991), fighting for equality while claiming difference, and demanding political representation, while insisting on its material and historical specificity. Queer celebrated the diversity of subjects who experienced heterosexist oppression without essentializing identity, while at the same time acting as an umbrella term for all those who had been marginalized because they transgressed the heterosexual norm (Khayatt, 2002). Intersectionality's project was to celebrate diversity without conflating identities or creating hierarchies of oppressions, while at the same time acting as an umbrella term for the expressed experience of multiple oppressions. The multiple identities of oppression formed an axis that amplified the magnitude of social inequalities one experiences through categories of oppression that are shaped by one another rather than as a single, discrete, and unrelated event (Crenshaw, 1989).

A queer theoretical practice that operates through an intersectional lens becomes a useful tool for making visible how some desirous subjects pass as normal and how others are rendered marginal. This plays out in countries where the rights of queer citizens are protected, while racialized queers are still experiencing discrimination within these communities. It allows people to see how both social processes and social representation are crucial in the understanding of oppression. Without a doubt, queer can be seen as a term that negatively erases difference, but I am holding on to the utopian use of the term, which is theoretically structured around the concept of intersecting identities as they relate to sexuality.

Readers can also understand queer theory by looking at how it functions. It is my view that queer theory performs as a constant narrative with the power to challenge all norms relating to sexual identity. Intersectionality accounts for the multiple levels across which oppression operates, and queer theory pushes us to deconstruct categorical identities and question normativity. Intersectionality articulates the site of becoming marginalized or oppressed, while queer theory allows us to question norms that perpetuate marginalization or oppression. Together, these theories force us to ask different questions and ask questions differently (Coloma, 2006), and their theoretical systems can be combined not only for academic exercises and purposes, but also as political tools in the creation of epistemologies, social justice coalition building, and practices of resistance. Queer theory, then, can be seen as innovative because of the degree to which it facilitates self-consciousness about how society mediates self-understanding of sexual identities and for its promotion of queer culture building. By this I mean the radical project of recognizing identities, desire, and sex that can exist when the heterosexual subject is not the referent point or the normal discussant of sexual culture.

An intersectional queer theory is a transformative political project that can be used as a critical lens in scholarly practices to decenter the practice of naming mainstream queer subjects as having fixed definitions within collective queer identities or what I also term queer communities of necessity or survival, where diversity is overlooked in favor of gaining perceived monolithic political power. I want to develop a queer academic tradition that focuses on the lived experience of structural inequalities in order to reconceptualize the queer subject as embedded in difference and cultural diversity. It is important to refocus the emphasis on the everyday lives and intimate experiences of those who practice a queer tradition and to take into account the other identities that intersect to place them queerly in the world.

Queer Repositioning

I know that if queer theory is to be truly seen as innovative and to challenge what is 'normal,' it must provide a framework within which to challenge racist, misogynistic, and other oppressive discourses, as well as those that are heterosexist and homophobic, through an intersectional lens. It cannot simply challenge heteronormativity but must instead question and resist the very systems that sustain heteronormativity. There needs to be a clear understanding of the ways in which systems of oppression are linked and create discourses that seek to undermine and expose the entire system through frameworks that address both local and global sexual identities as well as offer ways of moving toward nonoppressive practices.

I have been focusing on the ability of this theory to articulate both a sexual culture and a movement of political resistance, as well as demand a change in sexual politics. Queer theory mirrors the discourse of white gay and lesbian historiography and sociology, both of which have haphazardly added on marginalized groups such as racialized communities as an afterthought with little or no understanding of sociosexual specificity. According to Escoffier (1990), queer theory has placed emphasis on the intellectualized interpretations of texts rather than on the social history or the sociology of gay life. He also notes that this queer theory at this point had failed to incorporate women and people of color in any significant way and postmodern theoretical concepts make interpretation difficult and obtuse for anyone outside of the academy.

I have set up the concept of queer theory to deliver so much, despite the fact that it is a theoretical framework that is thoroughly embedded in white Western academic culture. Those pioneers who produced queer theory have made abstractions of queers of color in particular (Berube, 2001). This reality forces us to investigate and explore how queer theory can be circulated and, at the same time, moved away from its origins in order to be used critically and for the development of oppositional practices. The thought being that in order to increase the political usefulness of queer theory, there needs to be mindful consideration that the theory as a framework has been disciplined by academia.

Just as heterosexuality limits the discourse on other sexualities, the structuring of queer theory around whiteness, for example, limits racial or ethnic discussions of queerness. The continued constructed silence around race and non-Western queer perspectives, or those identities that have not been constructed by Western definitions of sexuality and sexual identity

essentially forces us to essentialize our identities as ethnic and racialized queer communities. This flags how racialized groups are yet again being left out of another theoretical framework. This makes it a priority to investigate exclusion within frameworks that address sexuality and the importance of queer approaches to highlighting the marginalization of certain categories and experiences within its own movement.

At the same time I call into question the use of 'queer theory' as a tool to articulate the lives of racialized queers and also critique the concept of queer resistance or queer liberation. Valdes (2002) wonders whether queer liberation is possible without reference to gender, race, or class. If queer liberation only stands for sexual liberation, then what kind of foundation is it standing on if it is supporting and perpetuating queer male privilege, class privilege, and/or white privilege? There can no longer be a universal category of 'queer' that includes all queers with gender, race, and ethnicity, for instance, being subsumed under some neutral umbrella and used merely as a descriptor. In the critical project that I am proposing, gender, race, and ethnicity are central to the content of a queer theoretical framework.

This debate has existed since the emergence of queer theorizing. Hammonds (1994) suggests that the use of the term queer without the qualifier 'black' first of all highlights the lack of meaningful theoretical engagement with the intersectionality of race and sexuality. For her, the term lesbian, for example, without the racial qualifier can be simply read as white lesbian. What methodologies, then, need to be created to read and understand how sexualities shaped by silence, erasure, and invisibility coexist with other sexualities and address the impact that the visible has on the invisible? Hammonds (1994) articulates this thought: "When I am asked if I am queer I usually say yes even though the ways in which I am queer have never been articulated in the body of work that is now called queer theory" (p. 1).

In queer theory, questions of race and ethnicity tend to be overlooked in order to analyze sexuality in the same manner that race-based scholarship tends to minimize the importance of sexuality and erase homosexuality from its analysis (Somerville, 2000). The notion of race must be central in the historicity and representational formation of a sexuality shaped by Black femaleness and compulsory heterosexuality. Such an analysis shifts queer theories' gaze from the resistance of mainstream heterosexuality to the elaboration of one's identity being located in constantly shifting intersections of oppression that are not only resisting heterosexuality, but other queers as well. As Hammond says:

> Torn between the homophobia of the black community and the racism of the white lesbian community, I need, as a black lesbian, to speak for myself and in my own voice, which is not the voice of the white world." While she does not doubt the good intentions of her colleagues, she does doubt their ability to understand her lesbianism which cannot be taken out of her context as a black woman: "I do not want my black experience filtered through your white academic language, the rage and passion edited out, explained away" (p. 88).

I use this example to propose the implementation of a logic that requires a critical reassessment of the ways in which queer individuals understand and pursue their history, politics, and sexualities and to articulate them in terms of the very differences that characterize queer communities and membership in them. This logic sheds light on the dynamics of heterosexism, homophobia, coming out, and existence in families as well as communities in specific gendered, racial, and ethnic contexts. It will help all individuals move away from primary resistance to negative images of nonwhite or non-Western queer identity toward challenging queer theory that lacks gendered, racial, and ethnic dimensions.

Intersectional Queerness

It might be useful to think of the articulation of an intersectional queer framework as a project of elaboration since the politics of marginal sexualities has not been so much neglected as it has been shielded from public view. Many members of society think that sexuality is a very 'straight'forward political matter and that queer people should not be discriminated against and that is as far as their political interest as a group should go. The question still remains as to whether or in what context do queers have political interests that connect them to broader demands for justice and freedom. Warner (1991) asks the simple but poignant question, 'What do queers want (p. 3)?' Any person who comes to a queer understanding of themselves understands that his/her oppression is connected but not limited to desire, family, fear, shame, health, personal freedom, gender, reproductive rights, parenting, silence, invisibility, public display, terror, violence, intimacy, depression, love, and marriage (GLAD, 2004). Being queer means to address these issues all the time, and deal with the ensuing consequences. As queer activists from non-Western contexts become more and more involved in setting political agendas and, as the rights discourse of internationalism is increasingly extended to more cultural contexts, mainstream queer theorists will have to become more conscious of the limiting localizing tendencies of their theoretical language.

An intersectional queer theory not only allows for the articulation of the lives of complex racialized subjects, but also challenges the mainstream frame of reference. It does not allow for the recycling sociosexual and socioeconomic hierarchies of oppression, which are fought against. The use of the term queer is based on a particular historical experience and many marginalized communities have limited if any historical connection with the term (Walcott, 2006). How, then, do marginalized communities insert themselves into this discussion and how do they lay claim to the discourse? I would say that there is need to interrogate the complex system of sexual norms within all cultures, where the normal racialized subject is not queer and the normal queer is not racialized. To firmly locate queerness in a historical, political, and intellectual context, and to identify the culturally based problematic that queer theory intends to remedy, theorists must determine what Penn (1995) would define as the conceptual category of intersectional queerness.

A poststructural approach to sexuality understands that there is neither true queer history but many histories nor is there a true queer identity but many identities that are fluid and dynamic. One needs to question whether it is a personal, political, or linguistic one? For you to call yourself queer possibly means that you are a certain type of person, that you

engage in certain sexual behaviors, that you will have a certain kind of political orientation, and that you will potentially dress in a particular type of way and look a certain way. Until a word gains wide usage in the culture, the category, identity, or type of person it represents does not exist (Khayatt, 2002). Queerness is socially constructed and cannot be understood without recognizing that an identity and the resulting behavior are derived from social norms. Being queer entails the realignment of identity, politics, and desire as one moves between cultures, regions, and nations (Massaquoi, 2013). For example, within the vastness of languages in the African continent, the term 'queer' could be theoretically interchanged with the terms buyazi, mashoga, tousso bakari, woubie, supi, or kuchu, to name a few. What does it mean to be queerly marked and to answer to those terms in Africa? What happens when that queerly marked African body becomes transnational in a Western context? It involves answering to those terms, acting on emotions, feeling desire, and engaging in the sexual practices that have different meanings, depending on the locality and the circumstances.

With the emergence of the queer refugees in the West, theoretical changes to political and culturally based approaches are required to allow for the articulation of identity, the claiming of space in queer history, and the creation of a political platform in terms of rather than in spite of the dissention that marks them differently from the mainstream queer communities. With this emergence, the complex system of sexual norms in both the refugee's country of origin and country of adoption requires interrogation. The queer refugee is traveling to Western destinations in which queer subjects are fighting for political rights and freedoms for the mainstream white queer communities while often engaging in discriminatory exclusionary patterns of behavior that disregard and invalidate the issues and experiences of queer transnationals (Patton and Sanchez-Eppler, 2000). It is often the case that queer refugees are coming from nations in which there are widespread beliefs supported by religious institutions, cultural norms, and political leadership that homosexuality does not exist, and that it is a Western construction or a Western disease (Hoad, 2007).

Thus, one of the biggest challenges for queer subjects globally is forced invisibility. By using an intersectional lens in the development of queer theoretical frameworks, invisibility could become the starting point for launching a discussion of same-sex desire in which queer refugees could be central figures. This is something that traditional queer theory is unable to accommodate. The queer refugee is invisible in both the country of origin and the country of adoption. Addressing this invisibility becomes the point from which the work of identifying the ways in which queer refugee subjects occupy a perverse subject position begins. Reimagining and reconstituting their relationships within multiple identities and interrogating how nonnormative erotic and gender configurations erupt within sites of extreme heteronormativity will lead to change. A queer theory that is not conscious of the privileging of Western definitions of same-sex sexual practices and experiences risks duplicating an imperial gaze in relation to non-Western sexual practices and identities. An intersectional queer theory would then be required to function not as an autonomous narrative but as one that is enmeshed and immersed within multiple discourses.

Identity based on same-sex desire may be potentially productive of new forms of self, community, and social relations. Bannerji (1993) comments on her disconnection from the white queer androgynous esthetic as she adorns herself in traditional South Asian attire, which has multiple readings for her as a South Asian Canadian lesbian but read as a 'femme' or hyperfeminine identity in a white lesbian context. She challenges the roles and behaviors attributed to that presentation, which complicates her attempt to negotiate ethnicity and sexual identity in a Western context. Queer theory speaks to the need for a particular strategy of reading sexuality outside dominant configurations of visibility, same-sex desire, and identity within cultures and against other cultures. It speaks to Foucault's 'paramount moment of possibility,' the positioning of bodies and pleasures that are not already enmeshed in the discourse of queer theory (Foucault, 1990).

One of the biggest challenges facing any project that attempts to dismantle or interrogate a system in which one group dominates another is to provide for a new system that does not reproduce the structure of the old one (Fanon, 1963). In proposing a need for an intersectional reading of queer theory to emerge, there must be a strategic effort to avoid simply assimilating dominant Western culture and essentializing notions of queer identity. Theorists must become fluent in each other's histories if the goal is to undo the ingrained mythologies that constrain us (Alexander, 1997).

Queer theory aims to identify some of the changes in political and cultural approaches that are necessary for realizing such potential. These changes, I believe, will facilitate positive modes of thinking and behavior that exceed the current exclusionary logic. Heterosexism, for example, can be overcome only by actively imagining a necessarily and desirably queer world (Warner, 2002). This project highlights that any movement of queer liberation cannot be representative without proactively addressing community building, providing the tools for communities to do so, and reaching beyond the intellectual landscape of academic theories to impact the day-to-day lives and practices of queers. It requires looking at the rearticulation and reconfiguration of queer lives that do not necessarily resolve or dissolve their conflicts and tensions but instead refashion them into proactive patterns of thought and behavior.

Conclusion

By expanding the ways of thinking about queerness, queer theories will be opened up to a wider audience (Valdes, 2002). Queer theory does its work by contributing to diverse and sometimes conflicting projects, across interdisciplinary academic fields. Under contemporary social and political conditions, queer theory cannot be understood as ideal in its resistance to heteronormativity, but can ask what the possibilities are for the theory's expansion in a given political moment. What are the possibilities, conditions, and future imaginations of a queer theory that can thoroughly embrace intersectionality? There needs to be an engagement in intersectional bound self-discovery, which involves the understanding of what it means to be an individual whose multiple identities have been imposed upon or premised on exclusion

and invisibility to create a subordinate other who can also recreate the self by acts of refusal. The conceptualization of intersectional queer subjects displaces the neutral (read white) heterosexual norm and launches a critique of queer theory from the locational politic where it is articulated. Collective queer identities acquire specific content from the narratives of both belonging and exclusion and become strategically essentialized as a necessary component of agency, resistance, and survival. It is an identity that is attained through an ongoing process of interpretation of social position and multiple intersecting social locations.

Questionnaires: Cognitive Approaches

Abstract

Respondents' answers to standardized questions presented in self-administered questionnaires or face-to-face and telephone interviews are a major source of social science data. These answers, however, are profoundly influenced by characteristics of the question asked, including the wording of the question, the format of the response alternatives, and the context in which it is presented. The cognitive and communicative processes underlying these influences are increasingly well understood, and this article reviews their implications for question wording and questionnaire construction.

Respondents' Tasks

Answering a question requires that respondents (1) interpret the question to understand what is meant and (2) retrieve relevant information from memory to form an answer. In most cases, they cannot provide their answer in their own words but (3) need to map it onto a set of response alternatives provided by the researcher. Finally, (4) respondents may wish to 'edit' their answer before they communicate it to the interviewer for reasons of social desirability and self-presentation. Respondents' performance at each of these steps is context dependent and profoundly influenced by characteristics of the questionnaire (Sudman et al., 1996, Chapter 3), including its administration mode (self-administered or a face-to-face or telephone interview).

Understanding the Question

The key issue at the question comprehension stage is whether respondents' understanding of the question matches the meaning the researcher had in mind. Not surprisingly, methodology textbooks urge researchers to write simple questions and to avoid unfamiliar or ambiguous terms (for good practical advice, see Bradburn et al., 2004). However, understanding the *literal meaning* of a question is not sufficient to provide an informative answer. When asked, "What have you done today?" respondents are likely to understand the words – yet, they still need to determine what kind of activities the researcher is interested in. Should they report, for example, that they took a shower, or not? Providing an informative answer requires inferences about the *questioner's intention* to determine the *pragmatic meaning* of the question.

To infer the pragmatic meaning, respondents draw on a broad range of contextual information, including the content of adjacent questions, the nature of the response alternatives, and the graphical layout of questions. Their use of this information is licensed by the tacit assumptions that govern the conduct of conversation in daily life, which respondents apply to the research interview (Clark and Schober, 1992; Schwarz, 1996). These pragmatic inferences have important implications for questionnaire construction.

Question Context

Respondents interpret questions in the context of the overall interview and a term like 'drugs' acquires different meanings when presented in a survey pertaining to respondents' medical history rather than to crime in the neighborhood. Moreover, they assume that adjacent questions are meaningfully related to one another, unless otherwise indicated. They may infer, for example, that an ambiguous 'educational contribution' refers either to fellowships that students receive or to tuition they have to pay, depending on the content of adjacent questions (Schwarz, 1996, Chapters 3–4). Finally, they hesitate to reiterate information they have already provided, consistent with conversational norms that discourage redundancy. For example, questions pertaining either to happiness with one's life or to life satisfaction typically elicit highly similar answers unless both questions are presented together. In the latter case, respondents assume the researcher wouldn't ask for the same thing twice and differentiate between both questions, resulting in less similar answers (Schwarz, 1996, Chapter 6). In self-administered questionnaires, question interpretation is influenced by preceding as well as following questions, whereas only preceding questions can exert an influence in face-to-face and telephone interviews.

Response Alternatives

Most questions are presented with a fixed set of response alternatives, which facilitates administration and data analysis. Far from being 'neutral' measurement devices, however, response alternatives influence question interpretation (Schwarz, 1996, Chapter 5). First, consider the differences between *open* and *closed* response formats. When asked in an open response format, "What have you done today?" respondents are likely to omit activities that the researcher is obviously aware of (e.g., "I gave a survey interview") or may take for granted anyway (e.g., "I took a shower"). Yet, if these activities were included in a closed list of response alternatives, most respondents would endorse them. At the same time, such a list would reduce reports of activities that are not represented on the list, even if an 'other' option were provided, which respondents rarely use. Both of these question form effects reflect that response alternatives can clarify the intended meaning of a question by specifying what the researcher is interested in. When using a closed response format, it is therefore important to ensure that the list of response alternatives covers the full range of behaviors or opinions.

Similarly, suppose respondents are asked how frequently they felt 'really irritated' recently. To infer if 'really irritated'

refers to major or to minor annoyances, respondents may draw on an apparently formal feature of the question, namely the numeric values of the *frequency scale*. When the scale presents low- (high-) frequency alternatives, respondents infer that the researcher is interested in rare (frequent) events. Hence, they report on major annoyances (which are relatively rare) when given a low-frequency scale, but on minor annoyances when given a high-frequency scale. As a result, the same question elicits reports of substantively different experiences, depending on the frequency scale used (Schwarz, 1996, Chapter 5).

In sum, apparently formal differences in the response alternatives can profoundly influence respondents' interpretation of the question. Far from reflecting superficial responding, such effects indicate that respondents do their best to make sense of the question asked by drawing on the full range of information available to them – including information the researcher never intended to provide. To safeguard against unintended question interpretations, researchers have developed a number of different pretesting procedures, reviewed in Section Pretesting.

Age-Related Differences

Respondents' extensive use of contextual information requires that they hold the question in mind and relate it to other aspects of the questionnaire to determine its intended meaning. This entails considerable demands on respondents' cognitive resources. Given that these resources decline with increasing age, we may expect that older respondents are less likely to use, or less successful in using, contextual information at the question comprehension stage. Indeed, question order effects decrease with age, and this has a greater impact the poorer respondents' memory is (for a review, see Schwarz and Knäuper, 2000). Children and adolescents, whose cognitive capabilities are not yet fully developed, appear to show a similar deficit in incorporating relevant contextual information into survey responding (Fuchs, 2005). Age-related differences in the use of contextual information are more likely in face-to-face and telephone interviews, where respondents cannot look back to earlier questions, than in self-administered questionnaires.

Recalling or Computing a Judgment

Once respondents have determined what the researcher is interested in, they need to recall relevant information from memory. In some cases, respondents may have direct access to a previously formed relevant judgment that they can offer as an answer. In most cases, however, they will not find an appropriate answer readily stored in memory and will need to compute a judgment on the spot. The different judgmental processes pertaining to behavioral questions and opinion questions are discussed in Section Asking Questions about Behavior.

Formatting the Response

Unless the question is asked in an open response format, respondents need to format their answer to fit the response alternatives provided by the researcher. Respondents observe these *question constraints* and avoid answers that are not explicitly offered, as noted in Section Understanding the Question. For example, many more respondents answer, 'Don't know,' or choose a middle alternative, when these options are explicitly offered than when they are not (see Sudman et al., 1996, Chapters 3–4). Under which conditions the addition or omission of these response options results in different substantive conclusions is the topic of some debate.

Response-formatting processes are particularly relevant when *rating scales* are used (Sudman et al., 1996, Chapter 4). Specifically, respondents use the most extreme stimuli to anchor the endpoints of the scale. Hence, a given stimulus will be rated as less extreme if presented in the context of a more extreme one than if it is presented in the context of a less extreme one. In addition, if the number of stimuli to be rated is large, respondents attempt to use all categories of the rating scale about equally often. Hence, two similar stimuli may receive different ratings when only a few stimuli are presented, but may receive the same rating when a large number of stimuli has to be located along the scale. Accordingly, ratings of the same object cannot be directly compared when they were collected in different contexts, rendering comparisons over time or between studies difficult. The psychometric properties of rating scales have been the topic of extensive investigation (see Tourangeau et al., 2000, Chapter 8). Seven-point scales seem to be best in terms of reliability, percentage of undecided respondents, and respondents' ability to discriminate between scale points. Moreover, scales that provide verbal labels for each scale value seem more reliable than scales with verbal endpoints only.

Finally, respondents' choice of a given response alternative is often influenced by the order in which the alternatives are presented. Under the auditory presentation conditions of telephone interviews, a given alternative is more likely to be endorsed when it is presented last rather than first (referred to as a recency effect). Under the visual presentation conditions of a self-administered questionnaire, a given alternative is more likely to be endorsed when it is presented first rather than last (referred to as a primacy effect; see Sudman et al., 1996, Chapter 6, for a discussion of the underlying processes). Because limited cognitive resources make it more difficult to consider multiple response alternatives, response order effects increase with age and lower educational attainment, which can undermine group comparisons (see Schwarz and Knäuper, 2000).

Editing the Response

Finally, respondents may want to edit their response before they communicate it, reflecting considerations of social desirability and self-presentation (for a review, see DeMaio, 1984). Not surprisingly, the impact of self-presentation concerns is more pronounced in face-to-face interviews than in self-administered questionnaires. It is important to emphasize, however, that influences of social desirability are limited to potentially threatening questions and are typically modest in size. These influences can be reduced through techniques that ensure the confidentiality of the answer (for detailed advice, see Bradburn et al., 2004).

Asking Questions about Behavior

Most questions about respondents' behavior are frequency questions, pertaining, for example, to how often the

respondent has bought something or has missed a day at work during some specified period of time. Researchers would ideally like respondents to identify the behavior of interest, to scan the reference period, to retrieve all instances that match the target behavior, and to count these instances to determine the overall frequency of the behavior. This, however, is the route that respondents are least likely to take.

Except for rare and very important behaviors, respondents are unlikely to have detailed representations of numerous individual instances of a behavior stored in memory. Instead, the details of various instances of closely related behaviors blend into one global representation, rendering it difficult to distinguish and retrieve individual episodes. Accordingly, a 'recall-and-count' model does not capture how respondents answer questions about frequent behaviors or experiences. Rather, their answers are likely to be based on some fragmented recall and the application of inference rules to compute a frequency estimate. Accordingly, the best we can hope for under most conditions is a reasonable estimate, unless the behavior is rare and of considerable importance to respondents.

Conway (1990) provides an introduction to psychological research into autobiographical memory (i.e., individuals' memory for their experiences and behaviors), and Schwarz and Oyserman (2001), Sudman et al. (1996, Chapters 7–9), and Tourangeau et al. (2000, Chapters 3–5) review the implications for questionnaire construction. The following sections summarize what researchers can do to facilitate recall and review what has been learned about the influence of questionnaire characteristics on respondents' estimation strategies.

Facilitating Recall

Recall Cues and Reference Periods

If researchers are interested in obtaining reports that are based on recalled episodes, they may simplify respondents' task by providing appropriate *recall cues* and by restricting the recall task to a short and recent reference period. There are, however, important drawbacks to both of these strategies. Although the quality of recall will generally improve as the retrieval cues become more specific, respondents are likely to restrict their memory search to the particular cues presented to them, reflecting that the cues constrain the meaning of the question. As a result, respondents will omit instances that do not match the specific cues, resulting in underreports if the list is not exhaustive. Moreover, using a short reference period may result in many 'zero' answers from respondents who rarely engage in the behavior, thus limiting later analyses to respondents with a high behavioral frequency. Finally, reference periods of different lengths may result in different question interpretations: long reference periods (How often have you been angry last year?) suggest that the researcher is interested in relatively rare events, whereas short reference periods (How often have you been angry last week?) indicate an interest in frequent events. Hence, respondents may report on substantively different behaviors, for example rare and intense versus frequent but minor episodes of anger.

Not surprisingly, different recall cues are differentially effective. The date of an event is the poorest cue, whereas cues pertaining to what happened, where it happened, and who was involved have been found to be very effective. In addition, recall will improve when respondents are given sufficient time to search memory. Recalling specific events may take up to several seconds, and repeated attempts to recall may result in the retrieval of additional material, even after a considerable number of previous trials. Unfortunately, respondents are unlikely to have sufficient time to engage in repeated retrieval attempts in most research situations, and may often not be motivated to do so even if they had the time. This is particularly crucial in the context of survey research, where the available time per question is usually less than 1 min.

Moreover, the direction in which respondents search memory may influence the quality of recall. Specifically, better recall is achieved when respondents begin with the most recent occurrence of a behavior and work backward in time than when they begin at the beginning of the reference period. This presumably occurs because memory for recent occurrences is richer and the recalled instances may serve as cues for recalling previous ones. Given free choice, however, respondents tend to prefer the less efficient strategy of forward recall.

Yet, even under optimal conditions, respondents will frequently be unable to recall an event or some of its critical details, even if they believed they would 'certainly' remember it at the time it occurred. In general, the available evidence suggests that respondents are likely to underreport behaviors and events, which has led many researchers to assume that higher reports of mundane behaviors are likely to be more valid. Accordingly, a 'the-more-the-better' rule is frequently substituted for external validity checks.

Dating Recalled Instances

After recalling or reconstructing a specific instance of the behavior under study, respondents have to determine if this instance occurred during the reference period. This requires that they understand the extension of the reference period and that they can accurately date the instance with regard to that period. Reference periods that are defined in terms of several weeks or months are highly susceptible to misinterpretations. For example, the term "during the last 12 months" can be construed as a reference to the last calendar year, as including or excluding the current month, and so on. Similarly, anchoring the reference period with a specific date (Since March 1, how often …?) is not very helpful because respondents will usually not be able to relate an abstract date to meaningful memories.

The most efficient way to anchor a reference period is the use of salient personal or public events, often referred to as 'landmarks.' In addition to improving respondents' understanding of the reference period, the use of landmarks facilitates the dating of recalled instances. Given that the calendar date of an event will usually not be among its encoded features, respondents were found to relate recalled events to other, more outstanding events in order to reconstruct the exact time and day. Accordingly, using public events, important personal memories, or outstanding dates (such as New Year's Eve) as landmarks was found to reduce dating biases (for reviews, see Sudman et al., 1996; Tourangeau et al., 2000).

Without a chance to relate a recalled event to a well-dated landmark, time dating is likely to reflect both forward and backward telescoping. That is, distant events are assumed to have happened more recently than they did, whereas recent

events are assumed to be more distant than they are (Sudman et al., 1996, Chapter 8).

Calendar Methods

The currently most successful approach to improving autobiographical recall is offered by calendar methods that combine key characteristics of the above strategies in a single data collection format (see the contributions in Belli et al., 2009). To help respondents recall their alcohol consumption during the last week, for example, respondents may be given a calendar grid that provides a column for each day of the week, cross-cut by rows that pertain to relevant contexts. Thus, they may be asked to enter for each day what they did, who they were with, if they ate out, and so on. Reconstructing the last week in this way provides a rich set of contextual cues, with entries in one row often prompting memories relevant to a different row. Based on this rich network of associations, individual episodes are more likely to be retrieved than under other methods, and each recalled episode may prompt additional memories. The method also encourages respondents to correct earlier answers as additional information comes to mind. This approach is costly in terms of interview time, but excessive cost can be avoided by implementing it in self-administered or online formats.

Estimation Strategies

Even with extensive encouragement and opportunity to search memory, respondents will often need to rely on estimation strategies to arrive at an answer (Sudman et al., 1996, Chapter 9) – and under the time pressure of most survey interviews, estimation is more likely than detailed recall. Which estimation strategy they use is often a function of the research instrument and hence to some extent is under researchers' control.

Decomposition Strategies

Many recall problems become easier when the recall task is decomposed into several subtasks. To estimate how often she has been eating out during the last three months, for example, a respondent may determine that she eats out about every weekend and had dinner at a restaurant this Wednesday, but apparently not the week before. Based on such partial recall, she may arrive at an estimate of "18 times during the last three months." Such estimates are likely to be accurate if the respondent's inference rule is adequate, and if exceptions to the usual behavior are rare.

In the absence of these fortunate conditions, however, decomposition strategies are likely to result in incorrect estimates because people usually overestimate the occurrence of low-frequency events and underestimate the occurrence of high-frequency events. Hence, asking for estimates of a global, and hence frequent, category (e.g., 'eating out') is likely to elicit an underestimate, whereas asking for estimates of a narrow, and hence rare, category (e.g., 'eating at a Mexican restaurant') is likely to elicit an overestimate. The observation that decomposition usually results in higher estimates does not therefore necessarily reflect better recall (see Schwarz and Oyserman, 2001).

Subjective Theories

A particularly important inference strategy is based on subjective theories of stability and change (Ross, 1989). In answering retrospective questions, respondents often use their current behavior or opinion as a benchmark and invoke an implicit theory of self to assess whether their past behavior or opinion was similar to, or different from, their present behavior or opinion. The resulting estimates are correct to the extent that the subjective theory is correct. This, however, is often not the case.

In many domains, individuals assume a rather high degree of stability, resulting in retrospective reports that are too close to the current state of affairs, thus underestimating the degree of change that has occurred over time. For example, retrospective estimates of income or of tobacco, marijuana, and alcohol consumption were found to be heavily influenced by respondents' income or consumption habits at the time of the interview. On the other hand, when respondents have reason to believe in change, they will detect change, even though none has occurred. Assuming, for example, that therapy is helpful, respondents may infer that their problem behavior prior to therapy was more frequent than was actually the case. Relying on such theory-driven retrospective reports, researchers may infer therapeutic success where none has occurred (see Ross, 1989, for example).

Response Alternatives

In many studies, respondents are asked to report their behavioral frequencies by checking the appropriate alternative on a frequency scale of the type shown in Table 1. Assuming that the researcher constructed a meaningful scale, respondents commonly believe that the values in the middle range of the scale reflect the 'average' or 'usual' behavioral frequency, whereas the extremes of the scale correspond to the extremes of the distribution. Given this assumption, respondents can use the range of the response alternatives as a frame of reference in estimating their own behavioral frequency. This strategy results in higher estimates along scales that present high- rather than low-frequency response alternatives, as shown in Table 1. As may be expected, the impact of frequency scales is most pronounced for frequent and mundane behaviors, which are poorly represented in memory (for a review, see Schwarz and Oyserman, 2001).

Table 1 Reported daily TV consumption as a function of response alternatives

Reported daily TV consumption (in hours)

Adapted from Schwarz, N., Hippler, H.J., Deutsch, B., Strack, F., 1985. Response scales: effects of category range on reported behavior and comparative judgments. Public Opinion Quarterly 49, 388–395. Reprinted by permission.

In addition to influencing respondents' behavioral reports, response alternatives may also affect subsequent *comparative judgments*. For example, a frequency of '$2^1/_2$ h per day' constitutes a high response on the low-frequency scale, but a low response on the high-frequency scale shown in Table 1. Checking this alternative, a respondent may infer that her own TV consumption is above average in the former case, but below average in the latter. Hence, respondents in this study reported lower satisfaction with the variety of things they do in their leisure time when the low-frequency scale suggested that they watch more TV than most other people.

To avoid these systematic influences of response alternatives, it is advisable to ask frequency questions in an open response format, such as "How many hours a day do you watch TV? ___ hours per day." Note that such an open format needs to specify the relevant units of measurement, such as 'hours per day,' to avoid answers like 'a few.'

As another alternative, researchers are often tempted to use 'vague quantifiers,' such as 'sometimes,' 'frequently,' and so on. This, however, is the worst possible choice. Most importantly, the same expression denotes different frequencies in different content domains; for example, 'frequently' suffering from headaches reflects higher absolute frequencies than 'frequently' suffering from heart attacks. Moreover, different respondents use the same term to denote different objective frequencies of the same behavior. For example, suffering from headaches 'occasionally' denotes a higher frequency for respondents with a medical history of megrim than for respondents without that megrim history. Accordingly, the use of vague quantifiers reflects the objective frequency relative to respondents' subjective standard, rendering vague quantifiers inadequate for the assessment of objective frequencies, despite the popularity of their use (Pepper, 1981).

Pretesting

Given the complexity of the question-answering process, extensive pretesting is of paramount importance. Traditionally, questions were often assumed to 'work' if respondents could provide an answer. Recent psychological research, however, facilitated the development of more sensitive pretest procedures (for comprehensive reviews, see the contributions in Schwarz and Sudman, 1996; for good practical advice, see Willis, 2005). These procedures include the extensive use of probes and think-aloud protocols (summarily referred to as *cognitive interviewing*), detailed coding of interview transcripts, and the use of expert systems that alert researchers to likely problems. Drawing on these procedures, researchers can increase the odds that respondents understand the question as intended and use cognitive strategies that are likely to produce a meaningful answer.

Questionnaires: Collection of Subjective Expectations Data

Abstract

Questionnaires are used to elicit from individuals a broad array of objective information as well as subjective information about their thoughts and perceptions. This article focuses on a single topic about questionnaires – how to elicit respondents' subjective expectations of future events. Subjective expectations are being measured with increasing frequency, yet the social and behavioral sciences have not formed a common view on how expectations should be conceptualized and measured. A particularly intriguing controversy, described in this article, concerns the relative merits of verbal and probabilistic forms of questioning.

Questionnaires are used to elicit from individuals a broad array of objective information about their experiences and environments, as well as subjective information about their thoughts and perceptions. An important objective of social and behavioral science research is to make questionnaires more informative. In practical terms, how should the questionnaire be administered and what should be its content? Aspects of questionnaire administration include when and where the data are collected, who does the data collection, and the mode of administration (e.g., face-to-face, telephone, or the Internet). Aspects of content begin with the basic matter of determining the purposes of the questionnaire and end with specific issues of item wording, sequencing of questions, and formatting of responses.

This article focuses on a single topic about questionnaires – how to elicit respondents' subjective expectations of future events. For example, demographers ask women to predict their future fertility, political scientists ask citizens to predict their voting behavior, and economists ask persons to predict their future incomes. Researchers use the responses to expectations questions to predict these and other future events. They also use the responses to assess how individuals' expectations are related to the decisions they make today.

Subjective expectations of future events are being measured with increasing frequency. However, the social and behavioral sciences have not formed a common view on how expectations should be conceptualized and measured. A particularly intriguing controversy, described in this article, concerns the relative merits of verbal and probabilistic forms of questioning.

Subjective Concepts and Measures

A US National Research Council (NRC) panel study on *Surveying Subjective Phenomena* distinguished subjective from objective phenomena as follows (Turner and Martin, 1984, p. 8):

> Subjective phenomena are those that, in principle, can be directly known, if at all, only by persons themselves, although a person's intimate associates or a skilled observer may be able to surmise from indirect evidence what is going on 'inside.' Objective phenomena are those that can be known by evidence that is, in principle, directly accessible to an external observer.

The NRC panel acknowledged that the sharp dichotomy just drawn is not always tenable, but the essential idea clearly has content: subjective phenomena are not amenable to external verification.

The social and behavioral sciences have a common interest in understanding subjective phenomena, but the various disciplines have not been able to agree on concepts or measures. The conceptual problem is to characterize what is going on 'inside.' A reader of social and behavioral science research encounters an enormous variety of subjective concepts in use, with concepts that are central to one discipline often playing no role in others. A sense of this variety can be obtained by scanning the introductory chapter of Turner and Martin (1984), which mentions affect, aspirations, attitudes, disappointments, dispositions, emotion, frustrations, fulfillment, happiness, hopes, intentions, motives, opinions, plans, preferences, quality of life, satisfaction, and values. The measurement problem is to obtain empirical evidence on what is going on 'inside.'

A reader of empirical research in sociology, social psychology, or political science finds a long history of analysis of subjective data elicited from survey respondents through questionnaires. A reader of economics finds relatively little use of questionnaire responses until the early 1990s but a growing body of research since then. Economists long sought to infer subjective phenomena purely from observations of behavior and experiences but have increasingly become comfortable with measurement of expectations and some other subjective concepts. A reader of anthropology finds little reliance on questionnaire responses. Anthropologists, who tend to recoil from the tightly scripted structure of questionnaires, have preferred to elicit information through conversations.

To illuminate the diversity of perspectives on subjective phenomena, this article examines how different disciplines have used questionnaires to study subjective expectations about potential future events. How persons perceive the future is a shared concern of all social and behavioral science disciplines, yet there is a wide spectrum of views on how expectations should be conceptualized and measured.

Section Inference on Expectations in Economics examines the historical practice in economics of inferring expectations from realizations data, and recalls early efforts to collect data on economic expectations through questionnaires. Section Qualitative Attitudinal Research describes qualitative attitudinal research as practiced by sociologists and social

psychologists. Section Elicitation of Probabilistic Expectations describes the growing body of research in economics and cognitive psychology eliciting subjective probabilities of future events. Section Qualitative versus Probabilistic Expectations considers the relative merits of qualitative and probabilistic modes of questioning. Section Frontiers of Research discusses the frontiers of research on subjective expectations. See Manski (2004) for an extensive exposition of the subjects discussed below.

Inference on Expectations in Economics

Early in their careers, economics students are commonly taught that a good economist believes only what people do, not what they say. Skeptical of subjective data, economists have sought to infer expectations of future events by combining data on past experiences with assumptions about processes of expectations formation. This is a daunting task. To infer expectations from data on past experiences, economists must speculate about what information persons possess and how they use the available information to form their expectations.

Consider, for example, the matter of income expectations. Economists often assume that persons use their own past incomes to forecast their future incomes. Perhaps so, but how do persons form expectations of future income conditional on past income? Economists often assume that persons have *rational expectations*; that is, they know the actual stochastic process generating their income streams. Perhaps so, but what is this stochastic process? The practice has been to specify the income process up to some parameters and use available data on income realizations to estimate the parameters. Authors differ, however, in their specifications. Therefore, the literature displays competing models of expectations formation, with no clear way of distinguishing among them.

If inference on expectations from data on experiences is so challenging, why would economists not collect and analyze data on expectations? The answer lies at least partly in the history of a scientific controversy that began in the 1940s and persisted until the 1960s. In the 1940s, the US Federal Reserve Board began to fund an annual Survey of Consumer Finances, conducted by the University of Michigan Survey Research Center (SRC), that elicited qualitative assessments of expected household finances. A typical question took this form:

> How about a year from now – do you think you people will be making more money or less money than you are now, or what do you expect?

The usefulness of responses to such qualitative questions was controversial and the Federal Reserve Board appointed a committee to assess their value. The Federal Reserve Consultant Committee on Consumer Survey Statistics (1955) issued findings that questioned the predictive power of the SRC expectations data. The negative findings of the committee were challenged by SRC researchers, notably George Katona, a leading proponent of research on consumer attitudes and expectations. A contentious conference on expectations data followed (National Bureau of Economic Research, 1960). Then Juster (1964) reported an intensive study, drawing largely negative conclusions, of the usefulness of qualitative expectations data in predicting individual behavior.

The Federal Reserve – SRC controversy only concerned the usefulness of a certain type of qualitative expectations data in predicting consumer behavior. Academic economists, however, appear to have drawn the broader conclusion that all expectations data are suspect. Economists also failed to take note when Juster (1966) proposed elicitation of probabilistic expectations of consumer durable purchases and reported favorable empirical evidence. Exploration of this idea had to wait a quarter century, as described in Section Elicitation of Probabilistic Expectations.

Qualitative Attitudinal Research

The Federal Reserve – SRC controversy may have soured most economists on the usefulness of qualitative expectations data, but the collection and analysis of such data have long been important activities in other behavioral and social science disciplines. Many questions in common use have a structure similar to that of this General Social Survey (GSS) question eliciting expectations of job loss:

> Thinking about the next twelve months, how likely do you think it is that you will lose your job or be laid off – very likely, fairly likely, not too likely, or not at all likely?

This GSS question illustrates well a basic persistent problem that researchers face in interpreting qualitative expectations data – assessment of the interpersonal and intrapersonal comparability of responses. Respondents are often asked to report whether a specified event is 'expected,' 'likely,' or 'probable' to occur. Sometimes they are asked to report their strength of belief in the event on a numerical scale with undefined units. Do different respondents interpret these verbal phrases and numerical scales in the same way? Does a given respondent interpret them in the same way when asked about different events? Cognitive research does not give reason to think that responses should be or are comparable. Indeed, the available empirical evidence indicates that interpretations of qualitative expectations questions vary substantially between persons (Section Qualitative versus Probabilistic Expectations).

Concern about interpersonal comparability comes into even sharper focus when considering the events about which respondents are asked. Attitudinal researchers often ask respondents about vaguely defined future outcomes, as in this SRC question:

> Now looking ahead – do you think that a year from now you (and your family living there) will be better off financially, or worse off, or just about the same as now?

How should a respondent interpret the phrase "better off financially?" Do different respondents interpret it the same way? The data provide no way of knowing.

A second persistent problem in qualitative attitudinal research is that the coarseness of the response options limits the information contained in the responses. Consider, for example, the fertility question posed to female respondents in the annual June Supplement to the Current Population Survey of the US Bureau of the Census:

> Looking ahead, do you expect to have any (more) children?

> Yes No Uncertain

The three response options can express little of the richness of the uncertainty that women may perceive about their future childbearing. Savage (1971, p. 795) called attention to the problem when he observed that "Yes, No, or Maybe is Not Enough." Juster (1966) hypothesized that a person facing a Yes/No expectations question responds as would a statistician asked to make a best point prediction of a future random event. Manski (1990) formalized this hypothesis and derived an upper bound on the information about expectations a researcher can extract from responses to Yes/No questions.

Elicitation of Probabilistic Expectations

A growing body of research in economics and cognitive psychology elicits expectations in the form of subjective probabilities. For example, the Survey of Economic Expectations used this question to elicit expectations of job loss:

> What do you think is the percent chance that you will lose your job during the next 12 months?

The National Longitudinal Study of Youth: 1997 Cohort of the US Bureau of Labor Statistics elicited the fertility expectations of teenage (girls/boys) as follows:

> What is the percent chance that you will become the [mom/dad] of a baby sometime between now and when you turn 20?

Probabilistic questions of similar structure have been posed in other national surveys, such as the Health and Retirement Study, The Bank of Italy Survey on Household Income and Wealth, and the American Life Panel.

Expectations have been elicited for macroeconomic events (e.g., stock market returns), for risks that a person faces (e.g., job loss, crime victimization, and mortality), for future income (e.g., the earnings returns to schooling and Social Security benefits), and for choices that persons make (e.g., durable purchases and voting choices). The review articles of Manski (2004) and Hurd (2009) describe the emergence of this field of empirical research and summarize a range of applications.

The idea that probabilistic elicitation of expectations might improve on the traditional qualitative approaches of attitudinal research developed independently in economics and in cognitive psychology. In economics, the idea appears to have originated with Juster (1966), who recommended elicitation of purchase probabilities for consumer durable goods. Market researchers were immediately attracted to Juster's proposal, and elicitation of purchase probabilities has since become a common practice in market research. However, the idea that expectations might be elicited probabilistically from survey respondents did not draw serious attention within economics until the early 1990s, when economists began to reassess the discipline's self-imposed prohibition on the collection and analysis of subjective data.

Elicitation of subjective probabilities has a more continuous history of research in cognitive psychology. Psychologists have long conducted calibration studies assessing the accuracy of elicited expectations reports when the outcome is known. Lichtenstein et al. (1982) review findings from calibration studies dating back to 1906. The older studies mostly examined the accuracy of experts (e.g., weather forecasters' reported probabilities of precipitation), whereas more recent research typically analyzes the expectations of nonexperts, especially students situated in a cognitive laboratory.

Qualitative versus Probabilistic Expectations

Economists have embraced probabilistic measurement of expectations, whereas attitudinal researchers continue to pose questions that seek verbal responses. Psychologists use both practices.

There is reasonably widespread agreement that elicitation of probabilistic expectations has several desirable features. Perhaps the most basic attraction is that probability provides a well-defined absolute numerical scale for responses. Hence there is some reason to think that responses may be interpersonally and intrapersonally comparable.

A second attraction is that some empirical assessment of the internal consistency and external accuracy of respondents' expectations is possible. A researcher can use the algebra of probability (Bayes theorem, the law of total probability, etc.) to examine the internal consistency of a respondent's elicited expectations about different events. In those cases where probability has a frequentist interpretation, a researcher can compare elicited subjective probabilities with known event frequencies, as is done in calibration studies, and reach conclusions about the correspondence between subjective beliefs and frequentist realities.

A third consideration is the usefulness of elicited expectations in predicting prospective outcomes. Suppose that respondents have reasonably accurate expectations about the likelihood of future events. Then, as argued by Juster (1966), Savage (1971), and Manski (1990), numerical responses to probability questions should have more predictive power than do categorical responses to qualitative expectations questions.

These a priori desirable features of probabilistic expectations data must be weighed against a set of issues. Perhaps the most basic concern is that there is no direct way to assess how well elicited subjective probabilities reflect respondents'

thinking. Of course this concern is not specific to elicitation of probabilities. Interpretation of responses to subjective questions of any type runs up against the generic problem that a researcher cannot directly observe a respondent's thinking.

A specific concern in the elicitation of probabilities is that respondents may not think probabilistically about uncertain events. A large and diverse literature suggests that persons may think about uncertain events using less than the full structure of modern probability theory. If so, then questions eliciting precise probabilities force respondents to give point responses when only interval responses may be meaningful. In a study of rounding of probabilistic responses, Manski and Molinari (2010) first asked respondents to the American Life Panel to provide precise probabilities of future events and then gave them the opportunity to provide interval responses. They found that some respondents continued to provide precise probabilities but others reported intervals when permitted to do so.

Within cognitive psychology, there has long been controversy about the way in which humans internally represent their beliefs, and their ability and willingness to express their internal beliefs as numerical probabilities. Wallsten et al. (1993) reported that a majority of respondents prefer to communicate their own beliefs verbally and to receive the beliefs of others in the form of numerical probabilities. This asymmetry is intriguing but only marginally relevant to the design of expectations questions. The relevant question is not what communication mode respondents prefer to use, but rather what modes they are willing and able to use. Wallsten et al. (1993) reported that virtually all their respondents were willing to communicate their beliefs numerically, should the situation warrant it.

A related theme of cognitive research has been to learn how individuals associate numerical probabilities and verbal phrases such as 'very likely,' 'probable,' or 'rarely' (e.g., Wallsten et al., 1986). A central finding is that individuals vary considerably in the numerical probabilities that they associate with given verbal phrases. There is, however, controversy about the proper conclusion to be drawn. Should one conclude that individuals differ in their interpretation of verbal phrases, in their interpretation of numerical probabilities, or in their interpretation of both? The empirical findings are compatible with all these conclusions.

Frontiers of Research

Empirical research measuring expectations has made substantial progress and has informed social science on many important issues. Two frontiers of research warrant particular attention.

First, future research should do more to understand how persons form their expectations. Attitudinal researchers have given little systematic thought to this basic matter. Researchers who conceptualize expectations in probabilistic terms have not been able to agree on how persons update their subjective probabilities in light of new evidence. Economists and statistical decision analysts have commonly assumed that persons apply the Bayes rule to update their expectations. Psychologists have reported empirical evidence to the contrary, but the practical import of this evidence remains unsettled. Many social scientists hypothesize that persons form expectations by observation of the behavior and experiences of others in their environments. However, we know precious little about the nature of social learning processes.

Second, research on subjective expectations should aim at understanding how a person's perception of the future affects behavior. Economists suppose that youth make schooling choices based on their expectations of the returns to schooling relative to labor market activity. They also hypothesize that uncertainty about future income induces individuals to increase savings, thereby decreasing consumption. Criminologists suggest that perceived risks of crime victimization may cause individuals to take precautions in their daily activities. Public health researchers speculate on how perceptions of health risks affect smoking, drug use, and unprotected sexual behavior. To shed light on these and similar questions of practical import requires intensive collection and analysis of expectations and behavioral data.

The research of Delavande (2008) demonstrates what may be accomplished by using expectations data when studying behavior. Delavande studied women's choice of contraception methods. She assumed that women base their decisions on their beliefs regarding method-related outcomes, including pregnancy and contraction of a sexually transmitted disease (STD). To learn about these beliefs, she surveyed women and asked them to state their beliefs about the chance of becoming pregnant or contracting an STD if they were to use alternative contraceptive methods. She then combined the measured expectations with data on contraceptive behavior to estimate an econometric model of choice of contraceptive method. The availability of expectations data made it possible for her to identify preferences more persuasively than if she had made unfounded assumptions about expectations.

Abstract

This article gives a short biography of the Belgian mathematician, astronomer, and statistician Lambert-Adolphe-Jacques Quetelet and highlights his contributions to both theoretical and empirical foundations of a variety of social sciences (particularly sociology, demography, social statistics, and psychology). A bibliography is attached of selected works by Quetelet and of critical evaluations of his contribution. The article should also be of interest to historians of science.

Life and Career

Born in Ghent (Belgium) to a French father and Flemish mother, the young Quetelet started his career as a teacher, and besides his interest in mathematics, he also had artistic talents.

Quetelet was the first student to obtain a doctorate in 1819 at the newly founded State University of Ghent. In his dissertation he presented a new geometric function called the focal curve. In 1819 he was appointed mathematics professor at the Atheneum in Brussels and in 1820 he was elected to the *Académie royale des sciences et des belles-lettres.* The academy became the central place from which Quetelet directed all his other activities. In 1823 his scientific orientation took a decisive turn: he proposed the foundation of a new observatory to the Dutch government, and in the same year he was sent to Paris for further preparation of this plan. At the Paris observatory, contacts were established with Laplace, Poisson, and Fourier, and Quetelet's interests in probability theory and astronomy stem from this short period in France. The construction of the Brussels observatory was completed only in 1832, but in the meantime Quetelet had also become involved in the planning of the 1830 population census.

Unfortunately this census was never completed as a result of the Belgium's secession from The Netherlands in 1830. But, elected as secretary for life at the Academy in 1834, Quetelet remained in control not only of the activities in meteorology, astronomy, and physical geography located at the observatory, but also of the activities in demography and statistics at the *Bureau de Statistique* and, from 1841 on, at the *Commission centrale de Statistique.* The procedures to be used in the new census were tried out first in Brussels in 1842, and the nationwide census took place in October 1846. Both the method of census taking and the subsequent analyses with detailed breakdowns by age and marital status set new standards for similar undertakings in most other European countries. In the meantime Quetelet had gained an international reputation, first by the publication of his *Physique Sociale* in 1835, in which he brought together his earlier statistical work on demographic subjects, anthropometry, and criminology, and then by his relentless efforts to establish statistics as a new internationally oriented and empirically grounded scientific discipline. The latter was accomplished mainly through organizing a steady succession of international statistics conferences and by inspiring the foundation of statistical societies in other countries.

In 1855, however, Quetelet suffered a major stroke, and from then on his own scientific contribution was seriously reduced. But, until his death in 1874, he continued to inspire statistical applications in a wide variety of fields, and above all, to promote international comparability of statistical information. In Desrosieres' words (1993, p. 95), 'Quetelet was the orchestra conductor of 19th Century statistics.'

Quetelet's Contribution to Statistics and Demography

Quetelet's statistical work was profoundly influenced by early probability theory – particularly the binomial distribution of events with equal odds – and by the use that Laplace had made of the Gaussian bell curve in astronomy. From Laplace he had gained the insight that the binomial distribution could also represent measurement error in astronomical observations, and Quetelet was convinced that this would also hold for measurements in the physical, social, and 'moral' domains. In the 1820s, measurements and frequency distributions pertaining to these domains and based on large numbers were still very rare. Quetelet had to use the frequency distribution of the chest circumferences of over 5000 Scottish recruits to verify his hypothesis that these would conform to the binomial distribution (Hacking, 1990, pp. 108–111). In a series of heights of French recruits, however, he detected a deviation from the expected distribution and therefore suspected the presence of systematic errors associated with attempts to avoid conscription. This illustrates how Quetelet used theoretical distributions to assess measurement reliability.

His use of the bell curve led him also into far deeper water: he proposed the notion of *l'homme moyen* or the average man, of which all members of a given population would be imperfect copies. For Quetelet, and for many after him, the emergence of a bell curve is a strong indication that there must be a link between the individuals producing this particular frequency distribution. Individuals would be drawn as balls from the same urn, and populations would correspond to different urns. The average men, each reconstructed from a different population, would therefore facilitate comparisons between populations, which themselves would be sufficiently homogeneous. Quetelet's 'average man' has often been misunderstood and misused. First, Quetelet was never preoccupied exclusively by averages. Whenever possible he presented

complete distributions, and one of his contributions to demography is precisely his systematic presentation of *age-specific distributions* of vital events or of other occurrences (e.g., crime). This is the beginning of the statistical study of the life cycle. Second, Quetelet would be quite shocked to see his average man being associated with national prejudice, e.g., the stingy Scot, the thrifty Frenchman,…, for the simple reason that these would all be *unmeasured* attributes. In fact, he perceived his average man as an antidote against statements based on prejudice, anecdote, and impression. It is for this reason that Quetelet can be considered as one of the founding fathers of modern empirical sociology: adequate statistical measurement presupposes operationalization with satisfactory reliability and validity.

The most fundamental critique of the average man came from A. Lexis who discovered that the variances of observed distributions are generally too large to uphold the thesis of balls drawn from the same urn. The hypothesis of a homogeneous population ceased to be tenable, and this would have major consequences for the advancement of statistics and for theories in the biological and social sciences (cf. Desrosiéres, 1993: 111ff). In present day multivariate analyses we now routinely calculate 'little average men' in terms of subgroup means, odds ratios for different subpopulations at risk, and for different combinations of categories of co-variates. Furthermore, these numerous 'little average men' are compared and the results are tested for the presence or absence of significant differences.

The use of the bell curve was taken one step further by Quetelet's younger colleague and professor of mathematics at his alma mater in Ghent. PierreFrançois Verhulst (1804–49) imagined that the growth rate r of a population would evolve according to a normal distribution. The size of a population, or of any other stock, would then follow a logistic curve, i.e. the elongated S-curve, with 50 % of the total growth corresponding to the maximum of r, and then leveling off toward a saturation plateau. The logistic curve proved to have many applications: later demographic transitions produced population evolutions that very closely resemble the logistic curve, and diffusion processes modeled along the principle of contagion (of rumors, knowledge, disease, technology, etc.) or of competition commonly led to growth curves in accordance with Verhulst's logistic.

It is rather ironic that Verhulst's view of this particular form of population change did not feed back into Quetelet's own demographic work. Quetelet continued to think within the framework of a stationary population. Like several observers before him (e.g., Vauban, Sussmilch), Quetelet had been impressed by the observation that both numbers and distributions of vital events (deaths, births, marriages, ages at marriage, and age differences between spouses) showed a remarkable stability over time. His early work with Smits on the demography of the low countries had convinced him even more. Only major disturbances, such as a revolution, were capable of producing a temporary distortion (cf. his *causes constantes* et *causes accidentelles* in the *Physique sociale*). Quetelet kept thinking in terms of a homeostatic model, in the same way as Malthus had before him.

In his construction of the Belgian life table of 1841–50, centered around the census of 1846 and in his 'population tables' (population by age, sex, and marital status simultaneously) of 1850, Quetelet explicitly discusses the properties of a stationary population and shows that the actual age composition ought to be the same as the l_x or ${}_nL_x$ functions of the life table (l_x = number of survivors at each exact age x; ${}_nL_x$ = number of person-years lived in the age interval x to $x + n$). Furthermore, Quetelet goes on to show that the hypothesis of constant mortality could be relaxed (1835, p. 310; 1850, p. 16): 'the necessary condition for deducing a population table (i.e., an age structure) from a life table is that the deaths by age annually preserve the same ratios [in French: *rapports*] between them' (present author's translation and clarifications).

Quetelet was clearly on the way to show that there exists a neutral mortality decline which does not affect the shape of the age distribution (for the proof see A. J. Coale, 1972, pp. 33–36). What Quetelet never developed – probably because there was not yet a need for it in pre-transition Belgium – was the model of a stable population with a growth rate different from zero. Yet, his demographic work shows that he can be considered as an early founding father of the branch of contemporary demography called 'indirect estimation.' In this branch extensive use is made of population models (stationary, stable, quasistable), of model life tables, and of the mathematical properties of particular model distributions for detecting and correcting errors in recorded data, and especially for estimating basic demographic parameters of mortality, fertility, and nuptiality on the basis of fragmentary information. Modern historical demography and the demography of developing countries progressed rapidly thanks to these techniques and ways of thinking.

Quetelet's Contribution to Sociology

In contrast to Auguste Comte, Quetelet never developed a general plan for a new social science, and by 1900 many of his ideas had already become outdated (cf. J. Lottin, 1912, pp. 391–515). He is, however, highly typical of the beginnings of sociology: there is this new entity, called 'society,' that can be studied and analyzed from the outside with objective methods. This entity follows its own 'laws' (i.e., patterning, regularities) and these can be detected via statistical methods. At first, Quetelet's sociology had a deterministic ring, and his distinction between *causes constantes* and *causes accidentelles* led straight into the debate pitting collective determinism against individual freedom of action. Quetelet is clearly more impressed by the *causes constantes*, but in various places in his work he also proposed a solution to the conundrum. In an early letter to Villerme of 1832, for instance, Quetelet writes the following: "As a member of society [in French: *corps social*], the individual experiences at each moment the social requirements [la *necessite des causes*] and pays them regular tribute; but as an individual he masters these influences [*causes*] to some extent, modifies their effect and can seek to reach a superior state" (quoted in Desrosieres, 1993, pp. 103–104; present author's translation). In other words, through socialization the actor becomes an integral part of society, but individual and institutional agency (for Quetelet: the advancement of the sciences) play decisive roles in social change.

For many of his contemporaries the deterministic ring of the *Physique Sociale* of 1835 continued to be a source of steady criticism, particularly when Quetelet went on with his assertion that the *causes accidentelles* merely compensate each other. Later on, however, Emile Durkheim viewed the social influence on individuals and the feedback stemming from individual and collective action in very much the same way as Quetelet. Durkheim's equally holistic view of society, as in his *Formes élémentaires de la vie religieuse,* was directly influenced by Quetelet's work.

In actual practice, however, Quetelet remains essentially a master of 'comparative statics' rather than of 'social dynamics.' He paid little attention to the effects of early industrialization (definitely a *cause constante*) or to the impact of the economic, social, and health crises of the 1840s. This is very surprising for a chief statistician and demographer. The social reform movements, the rise in real wages, and the decline in adult mortality in Belgium since the 1860s also remain without comment. His successors in sociology were much more alert to analyzing the dynamics of the major societal transformations they were witnessing.

Contributions to Psychology

Quetelet's 1835 work on the development of human faculties has also had a major impact on the field of developmental psychology (Baltes, 1983; Lindenberger and Baltes, 1999). His work is the first effort to consider, based on empirical evidence, the nature of intellectual development from childhood into old age.

Treating human-ontogenetic development as a lifelong process is a fairly recent advent in psychology. Researchers in this field have been drawn to Quetelet's early efforts in this regard. They have also emphasized that Quetelet in his discussion of methodological issues was able to prefigure some of the issues that are of high significance for modern researchers. Among these are the role of period effects and selective survival.

Abstract

Queueing systems are simplified mathematical models to explain congestion. Broadly speaking, a queueing system occurs any time 'customers' demand 'service' from some facility; usually both the arrival of the customers and the service times are assumed to be random. If all of the 'servers' are busy when new customers arrive, these will generally wait in line for the next available server. Simple queueing systems are defined by specifying the following (a) the arrival pattern, (b) the service mechanism, and (c) queue discipline. From the probabilistic point of view, properties of queues are usually derived from the properties of stochastic processes associated with them. However, in all but the simplest queues, determination of the state probabilities is extremely difficult. Often, however, it is possible to determine their large time limit, the so-called equilibrium or steady-state distribution. This distribution does not depend on the initial conditions of the system and it is stationary. The ergodic conditions give the restrictions on the parameters under which the system will eventually reach the equilibrium. For the most part, queueing theory deals with computations of the steady-state probabilities and their use in computing other (steady-state) measures of performance of the queue. When only the expected values are required, an extremely useful formula for systems in equilibrium is Little's law. Most of the vast effort in queueing theory has been devoted to the probabilistic development of queueing models and to the study of its mathematical properties; that is, the parameters governing the models are, for the most part, assumed given. Statistical analyses, in which uncertainty is introduced, are comparatively very scarce. Inference in queueing systems is not easy: development of the necessary sampling distributions can be very involved and often the analysis is restricted to asymptotic results. The statistical analysis is simpler if approached from the Bayesian perspective.

Since Bayesian analyses are insensitive to (noninformative) stopping rules, all that it is required from the data is a likelihood function, which combined with the prior distribution on the parameters produces the posterior distribution from which inferences are derived. This is an important simplification in the analysis of queues where there are a variety of possible ways of observing the system, many providing proportional likelihood functions but very different sampling distributions. The prior distribution quantifies whatever is known about the system before the data is collected. Usually, there is plenty of information a priori about the queue, especially if it is assumed to be in equilibrium. However, it is also possible to keep the parallelism with a likelihood analysis and to avoid the incorporation of further subjective inputs, by carrying out a Bayesian analysis usually called 'objective' because the prior distribution used is of the 'noninformative' or 'objective' type. From the posterior distribution, computation of estimates and standard errors is immediate. Also, probabilities of direct interest (like the probability that the ergodic condition holds) can be computed. Most importantly, restrictions in the parameter space imposed by the assumption of equilibrium are readily incorporated into the analysis. Prediction of measures of congestion of the system (number of customers waiting, time spent queuing, number of busy servers, and so on) is carried out from the corresponding predictive distributions which are also very useful for design and intervention in the system.

The intuitive notion that everybody has of the so familiar 'queues' or waiting lines closely parallels its mathematical meaning. Queueing systems are simplified mathematical models to explain congestion. This is a field of impressive activity and growth, which has mainly been concerned with the building of the models and the study of its probability properties. Relatively little effort has been put into their statistical analysis. In this article, the main concepts underlying simple queuing systems are discussed; some Bayesian inferential tools are also given.

Queueing Systems

Broadly speaking, a queueing system occurs any time 'customers' demand 'service' from some facility; usually both the arrival of the customers and the service times are assumed to be random. If all of the 'servers' are busy when new customers arrive, these will generally wait in line for the next available server. In some examples, the terms 'customer,' 'service' and 'server' have the usual, everyday meaning. For instance, queueing systems occur when customers check out in a grocery store, or require the service of a teller in a bank; here, the queueing term 'customer' refers to the actual customers at the store or the bank, the required service is to be checked out or to resolve the bank inquiry they have, and if the server (the check-out person or the teller) is busy when a customer require his/her service, then the customer has to wait in line, that is, queue up for service. In general, the terms 'customers,' 'service,' and 'servers' are very broad and can refer to almost anything; for instance, telephone calls ('customers') arriving at a switchboard (the service time being the time each call needs to be completed), machine failures (the 'customer' is the machine, and the server the repair person), demands of CPU time (server is the CPU, and the service the completion of the task), etc. Sometimes, a 'waiting line' (real or conceptual) never occurs. For instance, buses following their route can be considered a queueing system in which the customers are the buses, and the service is the completion of the route; here, customers are immediately 'served' and no waiting is necessary (technically, infinite servers, or as many servers as the number of buses, are assumed). In many interesting applications, customers require more than one service from different servers, and upon completion of service in one node, they have to proceed to another node. If the new server is busy, the customer has to queue up again for service. This is a typical situation modeled by the so called networks of queues, which are not treated in this article. An example occurs when patients enter an emergency department in a hospital: they might have to 'queue up' for primary attention, X-rays, lab service, surgery, and so on.

Queues (and queueing networks) have become very useful tools for evaluating (at least approximately) the performance of complex interacting stochastic systems in which congestion occurs. Obvious applications occur in airport terminals, health-care centers, and check-out lines at different counters. They have also been traditionally applied to biology (migration, population models), electrical engineering (flow models) and chemistry (polymerization, clustering) among others. The most prevalent applications of queueing systems and networks occur in the fields of manufacturing, computer networking, and telecommunications and broadcasting. But there are also many applications in the social sciences:

1. Several types of airport queues: aircrafts waiting to take off or to land, queues of passengers at terminals (they have to go through ticket counters, check-in counters, security and passport controls, baggage carousels, customs, etc.).
2. Police, fire, and emergency medical systems can all be regarded as queueing systems. Here the main concern is with responding to the calls for assistance as quickly as possible, important questions being to decide the number of units and which unit or units to dispatch to a specific call.
3. Health-care systems provide many examples of analyses well suited for queueing systems, as modeling the movement of coronary patients in a hospital, determining the staffing of a department, modeling waiting queues for transplants, etc.
4. In justice scenarios, cases queue up for trial and the length of the trial depends on the actions of both the 'customer' (that is, the lawyers), and the judge.
5. Analyzing and evaluating the delays in the mail, studying queues at voting polls to optimize the number (and type) of voting machines, and so on.
6. Latent phase of diseases (such as Aids) in which the times of infection are arrivals to the queuing system, the incubation is the 'service,' and the onset (or diagnosis) of the disease is the departure from the queuing system. Questions of interest are the number of people in the system and the time that 'customers' stay in the system (that is, from infection to onset or diagnosis).
